Abstract

These notes are based on Jonathan Block's lectures for the course "Geometric Analysis and Topology II" given at UPenn along with Allen Hatcher's *Algebraic Topology*. Any mistake in what follows is my own.

Contents

1 Basic geometric notions

1.1 Lecture 1

Example 1. There are usually many different (continuous) maps between spaces, but finding a homeomorphism can be difficult or impossible.

1. $\mathbb{R}^n \not\cong \mathbb{R}^m$ when $n \neq m$.

2. "X" $\not\cong$ "Y" since removing the intersection point of the letter "X" produces four components whereas removing the intersection point of "Y" produces three.

3. $\{a, b\} \not\cong \{a, b, c\}$.

4. (Alexander horned sphere) Let X denote the limit of the following iterative construction starting with the unit ball D^3.

Figure 1: copied from Hatcher (171)

It turns out that $X \cong D^3$, so that $\partial X \cong S^2$.

Note 1. The following are types of spaces that we will care about.

1. Manifolds.

   Remark 1.

   Definition. A space X is *homogeneous* if for any $x, y \in X$ with $x \neq y$, there is some homeomorphism $f : X \to X$ such that $f(x) = y$ and $f(y) = x$.

   Proposition 1. Any connected manifold is homogenous.

   With respect to connected manifolds, we may thus restrict our attention to questions of global topology.

2. Algebraic varieties over $\mathbb{R}$ or $\mathbb{C}$.

   Example 2. Consider the affine variety $Z(xy) = \{(x, y) \in \mathbb{R}^2 : x = 0 \vee y = 0\}$. This is not homogenous, because of the singularity $(0, 0)$.

3. The Cantor set $\mathcal{C}$. This is the unique homeomorphism class of spaces that are compact, metrizable, and totally disconnected.

   Example 3. Given a prime p, complete $\mathbb{Q}$ endowed with the p-adic metric $|\cdot|_p$ to obtain the p-adic numbers $\mathbb{Q}_p$. Then the ring of p-adic integers $\mathcal{O}_p \subset \mathbb{Q}_p$ is the Cantor set.

4. CW-complexes (developed by J. H. C. Whitehead).[1]

Recall that an n-cell is a space homeomorphic to $\operatorname{Int} D^n$ where $D^n := \{x \in \mathbb{R}^n : |x| \leq 1\}$.

Start with a discrete set X^0, called a *0-skeleton*.

By induction, define the *n-skeleton* as

$$X^n = X^{n-1} \coprod_\alpha D^n_\alpha \Big/ {\sim}$$

where $\varphi_\alpha : S^{n-1} \to X^{n-1}$ is an *attaching map* and $x \sim \varphi_\alpha(x)$ for each $x \in \partial D^n_\alpha$. Then

$$X^n = X^{n-1} \coprod_\alpha e^n_\alpha$$

where each e^n_α is an n-cell.

Set $X = \bigcup_n X^n$ and endow it with the weak topology: A is open in X if and only if $A \cap X^n$ is open in X^n for each n.

Definition.

- If X is a CW-complex, then the *dimension of X* is the maximum dimension of cells of X.
- If X is a CW-complex consisting of only finitely many cells, then it is called a *finite CW-complex*.

Remark 2. Each cell e^n_α has a *characteristic map* $\Phi_\alpha : D^n_\alpha \to X$ given by the composition

$$D^n_\alpha \hookrightarrow X^{n-1} \coprod_\alpha D^n_\alpha \twoheadrightarrow X^n \hookrightarrow X.$$

This extends the attaching map φ_α and is a homeomorphism $\operatorname{Int} D^n_\alpha \to e^n_\alpha$.

Remark 3. If X is a CW-complex, then any function $f : X \to Y$ is continuous if and only if $f \restriction_{X^n}$ is continuous for each $n \geq 0$.

Example 4. The following are CW-complexes.

1. $\{p\}$

2. $S^0 = \{\pm 1\}$

3. Construct S^1 by adding semi-circles (i.e., 1-cells) above and below S^0.

4. Construct S^2 by adding hemispheres (i.e., 2-cells) above and below S^1.

5. Any orientable surface of genus g.

   Consider the case $g = 1$. Draw the torus $S^1 \times S^1$ as
   The frame and interior are homeomorphic to the 1-skeleton $S^1 \vee S^1$ and the 2-cell $\operatorname{Int} D^2$, respectively.

   Next, consider the case $g = 2$. Similarly, we can draw the two-holed torus as

---

[1] $\underbrace{\text{C}}_{\text{cell}}\ \underbrace{\text{W}}_{\text{weak}}$
Figure 2: copied from Hatcher (5)

This is clearly a two-dimensional CW-complex.

Proposition 2. Every manifold has a CW-structure.

Example 5.

1. The Cantor set does not have a CW-structure, because it is totally disconnected.

2. Consider the subspace of $\mathbb{R}^2$ known as the Hawaiian earring.

If this had a CW-structure, then the sequence $(\frac{2}{n}, 0)_{n \in \mathbb{N}}$ would not converge to $(0,0)$, which is absurd.

Definition. Let $f, g : X \to Y$ be maps. A *homotopy from f to g* is a map $H : X \times I \to Y$ such that $H(x, 0) = f(x)$ and $H(x, 1) = g(x)$ for each $x \in X$. We say that f is *homotopic to g*, written as $f \simeq g$.

Note 2. From now on, assume that every topological space is Hausdorff.

Definition. Let $A \subset X$ be a subspace. A *homotopy between f and g relative to A* is a homotopy F between f and g such that if $t \in [0, 1]$, then $F(x, t) = f(x) = g(x)$ for each $x \in A$.

Example 6. Let $X := D^2 \setminus \{0\}$. Define $f : X \to X$ by $f(r, \theta) = (r, \theta)$ and $g : X \to X$ by $g(r, \theta) = (1, \theta)$. Then the map $F : X \times I \to X$ given by $F((r, \theta), t) = (t + (1 - t)r, \theta)$ is a homotopy between f and g relative to $S^1 \subset X$.

Definition. A *deformation retraction of X onto $A \subset X$* is a map $F : X \times I \to X$ such that $F(x, 0) = x$ for each $x \in X$, $F(a, 1) = a$ for each $a \in A$, and $F(x, 1) \in A$ for each $x \in X$.

Example 7. The solid torus $S^1 \times D^2$ deformation retracts onto S^1, as does the solid coffee mug.

Definition. Two spaces X and Y are *homotopy equivalent* ($\simeq$) if there are maps $f : X \to Y$ and $g : Y \to X$ such that $f \circ g \simeq \mathbb{1}_Y$ and $g \circ f \simeq \mathbb{1}_X$.

Definition. A space is *contractible* if it is homotopy equivalent to $\{*\}$.

Lemma 1. Homotopy equivalence of maps is an equivalence relation.

Proof. Both reflexivity and symmetry are obvious. To check transitivity, suppose that $F : f \simeq g$ and $G : g \simeq h$. Define $H(x, t) = \begin{cases} F(x, 2t) & 0 \le t \le \frac{1}{2} \\ G(x, 2t - 1) & \frac{1}{2} \le t \le 1 \end{cases}$. Then $H : f \simeq h$, as required. $\square$

Proposition 3. Homotopy equivalence of spaces is an equivalence relation.

Proof. We have a category $h\mathbf{Top}$ with spaces as objects and homotopy classes of maps $X \to Y$ as morphisms. Then two objects are isomorphic if and only if they are homotopy equivalent. But it's clear that any categorical isomorphism is an equivalence relation. $\square$

1.2 Lecture 2

Example 8. Here are more CW-complexes.

1. Recall that $\mathbb{RP}^n \cong S^n/_\alpha$ where α denotes the antipodal map. Thus, $\mathbb{RP}^n \cong D^n/_\sim$ where $x \sim y$ iff $x, y \in \partial D^n$ and $x = -y$. This implies that $\mathbb{RP}^n \cong \mathbb{RP}^{n-1} \cup_\pi D^n$ where $\pi : \partial D^n = S^{n-1} \to \mathbb{RP}^{n-1}$ denotes projection. By induction, we have that

$$\mathbb{RP}^n \cong e^0 \cup e^1 \cup \cdots \cup e^n.$$

2. Recall that $\mathbb{CP}^n = \{ \underbrace{[z_0 : \cdots : z_n]}_{\text{homogeneous coordinates}} : z_i \in \mathbb{C}, (z_0, \ldots, z_n) \neq 0\}$. Note that $\mathbb{CP}^n \cong S^{2n+1}/_{U(1)}$. We see that $S^{2n+1} = \{(w, \sqrt{1 - |w|^2}) \in \mathbb{C}^n \times \mathbb{C} : |w| \leq 1\}$. When $(w, z) \in S^{2n+1}$ has $z \neq 0$, then $(w, z) \sim (x', y')$ for some unique $(x', y') \in D^{2n}$. Otherwise, $(w, z) \in S^{2n-1}$. This shows that $\mathbb{CP}^n \cong \mathbb{CP}^{n-1} \cup_\pi D^{2n}$ where $\pi : S^{2n-1} \to \mathbb{CP}^{n-1}$ denotes projection. By induction, we get

$$\mathbb{CP}^n \cong e^0 \cup e^2 \cup \cdots \cup e^{2n}.$$

Definition. A closed subspace A of a CW-complex X is a *subcomplex* if A equals some union of cells of X. In this case, the pair (X, A) is called a *CW pair*.

Proposition 4. Let X and Y be pointed CW-complexes. Let $A \subset X$ be a subcomplex.

1. $X \coprod Y$ is a CW-complex.

2. $X \vee Y$ is a CW-complex.

3. $X \times Y$ is a CW-complex.

   Note 3.

   (a) The topology of $X \times Y$ as a CW-complex may be finer than $X \times Y$ equipped with the product topology.

   (b) An uncountable product of CW-complexes under the product topology need not be a CW-complex.

4. $X/_A$ is a CW-complex whose cells are precisely those of $X \setminus A$ together with the 0-cell $\pi(A)$ and attaching maps are precisely $\pi_{n-1} \circ \varphi_\alpha$ where $\pi_{n-1} : X^{n-1} \to X^{n-1}/_{A^{n-1}}$ denotes projection and $\varphi_\alpha : S^{n-1} \to X^{n-1}$ is an attaching map.

   Example 9. $D^n/_{S^{n-1}} \cong S^2$ for any $n \geq 1$.

Definition. Given any space X, define the *cone of X* as

$$C(X) = X \times I/_{(x, 1) \sim (y, 1)}.$$

Lemma 2. $C(X)$ is contractible.

Proof. Define $H((x, t), s) = \begin{cases} (x, (1 - s)t) & t \neq 1 \\ (x, 1) & t = 1 \end{cases}$. $\qquad\square$

Definition. Given any space X, define the *suspension of X* as $S(X) = X \times I/_\sim$ where $(x, 0) \sim (x', 0)$ and $(x, 1) \sim (x', 1)$.

Example 10. $S(S^n) = S^{n+1}$.

Proposition 5. Both $C(-)$ and $S(-)$ preserve the property of being a CW-complex ("CW-hood").

Definition. Let $f : X \to Y$ be a map of spaces. Define the *mapping cylinder of f* as

$$\mathrm{Cyl}(f) = \left. (X \times I) \coprod Y \middle/ (x, 1) \sim f(x) \right.$$

Note 4. $\mathrm{Cyl}(-)$ need not preserve CW-hood.

Lemma 3. $\mathrm{Cyl}(f) \simeq Y$.

Proof. Define

$$f : \mathrm{Cyl}(f) \to Y, \quad (x, t) \mapsto f(x) \quad y \mapsto y$$

and

$$g : Y \to \mathrm{Cyl}(f), \quad y \mapsto y.$$

We see that $f \circ g = \mathbb{1}_Y$.

Exercise 1. Prove that $g \circ f \simeq \mathbb{1}_{\mathrm{Cyl}(f)}$.

$\square$

Example 11.

1. Consider the following subspace of $\mathbb{R}^2$, called the comb space.
   This deformation retracts onto $(0, 0)$ but not onto $(0, 1)$.

2. Let X denote the comb space. Rotate X clockwise by 180 degrees to obtain the space A. Set $Y = X \cup A$ and note that A is closed in Y. Then both A and Y/A are contractible, but Y is not.

Definition. Let the pair (X, A) consist of a space X and a subspace $A \subset X$. We say that (X, A) has the *homotopy extension property (HEP)* if we can fill the commutative diagram

of spaces where H is a given homotopy from $f \restriction_A$ to another map. The inclusion $\iota : A \to X$ is called a *cofibration* if (X, A) satisfies HEP.

1.3 Lecture 3

Lemma 4. The pair (X, A) has HEP if and only if $A \times I \cup X \times \{0\}$ is a retract of $X \times I$.

Proof.
($\Longrightarrow$) We have the commutative diagram

Then φ is a retraction as desired.
($\Longleftarrow$) By hypothesis, there is some retraction $r : X \times I \to X \times \{0\} \cup A \times I$. This enables us to fill the diagram

If A is closed then $H \cup f$ is certainly continuous. If A is not closed, then our argument needs to be more careful. $\qquad \square$

Example 12.

(a) $S^{n-1} \hookrightarrow D^n$ is a cofibration.

> *Proof.* We see that $S^{n-1} \times I \cup D^n \times \{0\}$ is a retract of $D^n \times I$ by the following radial projection from the point $(0, 2)$.

Figure 3: copied from Hatcher (15)

> In fact, setting $r_t(x) = tr(x) + (1 - t)x$ for each $t \in I$ defines a deformation retraction r of $D^n \times I$ onto $S^{n-1} \times I \cup D^n \times \{0\}$. $\qquad \square$

(b) If $A := \{0, 1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \ldots\}$, then $A \hookrightarrow I$ is not a cofibration.

Proof. Suppose, for contradiction, that there is some retraction $r : I \times I \to A \times I \cup I \times \{0\}$. For each $n \geq 1$, the set $c_n := [(\frac{1}{n+1}, 1), (\frac{1}{n}, 1)]$ is connected, so that $r(c_n)$ is connected as well. Thus, there exists $(x_n, 1) \in c_n$ such that $r(x_n, 1) = (x_n, 0)$. But then $(x_n, 1) \to (0, 1)$ whereas $r(x_n, 1) \to (0, 0)$. As $r(0, 1) = (0, 1)$, this contradicts the continuity of r. $\qquad\square$

(c) Let $f : B \to A$ be a map. Then $(\mathrm{Cyl}(f), B \times \{0\})$ satisfies HEP.

Lemma 5. Any CW pair (X, A) satisfies HEP.

Proof. Notice that $X^n \times I$ is obtained from $X^n \times \{0\} \cup (X^{n-1} \cup A^n) \times I$ by attaching a certain number of copies of $D^n \times I$ along $D^n \times \{0\} \cup S^{n-1} \times I$. Recall the deformation retraction r from Example 12(b). Thus, we obtain a deformation retraction r_n of $X^n \times I$ onto $X^n \times \{0\} \cup (X^{n-1} \cup A^n) \times I$.

Define $U_n = X \times \{0\} \cup (X^n \cup A) \times I$ for each $n \geq -1$ with $X^{-1} = \emptyset$. Note that $U_n = (X^n \times I) \cup U_{-1}$. Extend each r_n to the homotopy $\hat{r}_n : U_n \times I \to U_n$ given by setting $\hat{r}_n(x) = x$ for each $x \in U_{-1}$. This is continuous since A is closed and $(X^n \times I) \cap U_{-1} = X^n \times \{0\} \cup A^n \times I \subset X^n \times \{0\} \cup (X^{n-1} \cup A^n) \times I$. Then each $\hat{r}_n$ is a deformation retraction of U_n onto U_{n-1}. Perform $\hat{r}_n$ during the t-interval $[\frac{1}{2^{n+1}}, \frac{1}{2^n}]$. The infinite sequential concatenation R of the $\hat{r}_n$ is continuous at $t = 0$ when restricted to each $X^n \times I^2$ and is thus continuous on $\bigcup_n U_n = X \times I^2$. Therefore, R is a deformation retraction of $X \times I$ onto $U_{-1} = X \times \{0\} \cup A \times I$. $\qquad\square$

Definition. Let X be a space. Define $\pi_0(X) = {}^{X}\!/_{\sim}$ where $x \sim y$ iff $\exists \varphi : I \to X$ such that $\varphi(0) = x$ and $\varphi(1) = y$. Then $\pi_0(X)$ is precisely the set of path components of X.

Definition. Let $\gamma, \hat{\gamma} : I \to X$ be paths in X such that $\gamma(0) = \hat{\gamma}(0)$ and $\gamma(1) = \hat{\gamma}(1)$. A *path homotopy from* γ *to* $\hat{\gamma}$ is a homotopy $H : I \times I \to X$ such that $H(0, s) = \gamma(0)$ and $H(1, s) = \gamma(1)$ for each $s \in I$. In this case, we write $\gamma \simeq_p \hat{\gamma}$.

Proposition 6.

1. If $\gamma_0 \simeq_p \gamma_1$ and $\eta_0 \simeq_p \eta_1$, then $\gamma_0 * \eta_0 \simeq_p \gamma_1 * \eta_1$.

2. $(\gamma_0 * \gamma_1) * \gamma_2 \simeq_p \gamma_0 * (\gamma_1 * \gamma_2)$.

3. Any map $f : X \to Y$ induces a map $f_* : \pi_0(X) \to \pi_0(Y)$. If $\gamma_0 \simeq_p \gamma_1$, then $f \circ \gamma_0 \simeq_p f \circ \gamma_1$.

4. For any path $\gamma : I \to X$, the path $\eta(t) := \gamma(1 - t)$ satisfies $\eta * \gamma \simeq_p c_{\gamma(1)}$ and $\gamma * \eta \simeq_p c_{\eta(1)}$ where c_x denotes the constant path at the point $x \in X$.

Definition. Define the *fundamental groupoid of a space* X as the category $\Pi_1(X)$ with $\mathrm{ob}(\Pi_1(X)) = X$ and $\mathrm{Hom}_{\Pi_1(X)}(x, y) = \{[\gamma]_{\simeq_p} \mid \gamma \text{ is a path from } x \text{ to } y\}$. We make concatenation of paths the composition of morphisms.

Note 5. This is in fact a groupoid in the sense of category theory.

Definition. Given $x_0 \in X$, define the *fundamental group of the pointed space* (X, x_0) as

$$\pi_1(X, x_0) = \mathrm{Hom}_{\Pi_1(X)}(x_0, x_0).$$

Note 6. The elements of $\pi_1(X, x_0)$ are precisely ${}^{\{\gamma : S^1 \to X \mid \gamma(1, 0) = x_0\}}\!/_{\simeq \, (\mathrm{rel}\,(1,0))}$

Proposition 7. If there is some path p from x to y in X, then $\pi_1(X, x) \cong \pi_1(X, y)$.

Proof. Define $\varphi_p : \pi_1(X, x) \to \pi_1(X, y)$ by $\gamma \mapsto p^{-1} \gamma p$. This is an isomorphism. $\qquad\square$

Remark 4. Any map $f : X \to Y$ induces a functor $f_* : \Pi_1(X) \to \Pi_1(Y)$ that restricts to a homomorphism $f_* : \pi_1(X, x_0) \to \pi_1(Y, f(x_0))$.

Theorem 1. If $n \geq 2$, then $\pi_1(S^n, x) = 0$.

Proof. Note that if $\eta : I \to S^n$ satisfies $\mathrm{im}\,\eta = S^n \setminus \{p\}$ for some $p \in S^n$, then $\eta \simeq_p c_x$ since $S^n \setminus \{p\} \cong \mathbb{R}^n$. Thus, it suffices to prove the following lemma.

8

Lemma 6. Every path γ in S^n is path-homotopic to some path η in S^n such that $\operatorname{im} \eta \neq S^n$.

Proof. Write $\gamma(t) = (\gamma_0(t), \gamma_1(t), \ldots, \gamma_n(t))$. The Weierstrass approximation theorem implies that we can approximate each γ_i by some smooth function. Hence we may find some smooth map $\tilde{\gamma}$ such that

$$|\gamma(t) - \tilde{\gamma}(t)| < \epsilon$$

for each $t \in I$. Now, there is some smooth retraction $r : D^{n+1} \setminus \{0\} \to S^n$. Define $H : I \times I \to S^n$ by

$$(t, s) \mapsto r(s\tilde{\gamma}(t) + (1 - s)\gamma(t)).$$

This is a homotopy $\gamma \simeq_p r \circ \tilde{\gamma}$. But $r \circ \tilde{\gamma} : I \to S^n$ is smooth and $n > 1$. By Sard, it follows that $\operatorname{im}(r \circ \tilde{\gamma})$ has measure zero in S^n. Thus, $r \circ \tilde{\gamma}$ is not surjective, as desired. $\qquad\square$

$\hfill\square$

1.4 Lecture 4

Theorem 2. If the pair (X, A) has HEP and A is contractible, then the natural projection $X \twoheadrightarrow {}^X\!/_A$ is a homotopy equivalence.

Proof. There is some contraction $H : A \times I \to X$ of A onto, say, a_0. We can find some map $\widetilde{H}$ such that

commutes. Then $\widetilde{H}_0 = \mathbb{1}_X$, and $\widetilde{H}_t(A) \subset A$ for each $t \in I$. By the universal property of quotient spaces, we get some $\bar{H}_t$ such that

commutes for each t. Since $\widetilde{H}_1(a) = a_0$ for each $a \in A$, it follows that

commutes as well for some map p. If q denotes the natural projection, then

$$q \circ p(\bar{x}) = q \circ p \circ q(x) = \bar{H}_1 \circ q(x) = \bar{H}_1(\bar{x}).$$

Then p is homotopy inverse to q. $\hfill\square$

Proposition 8. If X is contractible, then $\pi_1(X, x_0) = 0$.

Proof.

Lemma 7. Let $F : I \times I \to X$ be any homotopy. Let $\gamma := F \restriction_{\{0\} \times I}$, $\beta := F \restriction_{I \times \{1\}}$, $\delta := F \restriction_{\{1\} \times I}$, and $\alpha : F \restriction_{I \times \{0\}}$. Then $\beta \simeq_p \gamma^{-1} * \alpha * \delta$.

Proof. Write $\gamma(1) = x_0$ and $\delta(1) = x_1$. Define the path homotopies

$$G(s,t) = \begin{cases} x_0 & s \leq t \\ \gamma(1+t-s) & s \geq t \end{cases}$$

and

$$H(s,t) = \begin{cases} x_1 & 1-s \leq t \\ \delta(s+t) & 1-s \geq t \end{cases}.$$

Then $G : c_{x_0} \simeq_p \gamma^{-1}$, and $H : c_{x_1} \simeq_p \delta$. Hence

$$\beta \simeq_p c_{x_0} * \beta * c_{x_1} \simeq_p \gamma^{-1} * \alpha * \delta,$$

as desired. $\qquad\square$

By hypothesis, there is some contraction $F : X \times I \to X$ of X onto, say, the point x_0. Let $\gamma : I \to X$ be a loop at x_0. Then we get a homotopy $G : \gamma \simeq c_{x_0}$ where each G_t is a loop in X. Since $\eta := G\upharpoonright_{\{0\} \times I} = G\upharpoonright_{\{1\} \times I}$, our lemma implies that $c_{x_0} \simeq_p \alpha^{-1} * c_{x_0} * \alpha \simeq_p \gamma$. $\qquad\square$

2 Covering spaces

Definition. We say that a map $p : Y \to X$ is a *covering projection* if for each $x \in X$, there is some neighborhood $U \ni x$ such that

$$p^{-1}(U) \xrightarrow{\;\cong\;} U \times S$$

commutes for some discrete set S. We call a triple of the form $(X \times S, X, \pi_1)$ a *trivial covering space*. If every S has $|S| = n$ for some $n \in \mathbb{N}$, then p is called an *n-fold cover of X*.

Proposition 9. If $p : Y \to X$ is a covering projection, then Y is a manifold if and only if X is a manifold.

Example 13.

1. $p : \mathbb{R} \to S^1$ given by $x \mapsto e^{2\pi i x}$.

2. $p : S^1 \subset \mathbb{C}^\times \to S^1$ given by $z \mapsto z^n$.

3. $p : S^n \to \mathbb{RP}^n$ given as the quotient map is a 2-fold cover of $\mathbb{RP}^n$.

4. Let X be a space and Γ be a discrete topological group.

   Definition. A *group action on a space X* is an injective group homomorphism $G \to \mathrm{Homeo}(X)$.

   Let Γ act on the space Y such that for every $y \in Y$, there is some open set $U \ni y$ such that $g \cdot U \cap U = \emptyset$ when $g \neq e$. We call such a group action *a covering space action* or *properly discontinuous*. In particular, this action is free. Hatcher, Proposition 1.40(a) states that $Y \twoheadrightarrow {Y}/{\Gamma}$ is a covering projection.

   Remark 5. If Y is simply connected, then $\pi_1\left({Y}/{\Gamma}, y_0\right) \cong \Gamma$.

   Note 7. Let $\alpha \in \mathbb{R} \setminus \mathbb{Q}$. We have that $S^1 \cong {\mathbb{R}}/{x \sim x+1} \cong {\mathbb{R}}/{\mathbb{Z}}$. Let $\mathbb{Z}$ act on S^1 by $n \cdot [x] = [x + n\alpha]$. But note that for any $x \in S^1$, the orbit of x is dense in S^1 since α is irrational. Thus, ${S^1}/{\mathbb{Z}}$ has the indiscrete topology, and $S^1 \twoheadrightarrow {S^1}/{\mathbb{Z}}$ is not a covering projection.

Example 14. The following, however, are covering projections.

1. $\mathbb{R}^2 \twoheadrightarrow {\mathbb{R}^2}\big/{\mathbb{Z}^2} \cong S^1 \times S^1$.

2. $\mathrm{SL}_2(\mathbb{R}) \twoheadrightarrow {\mathrm{SL}_2(\mathbb{R})}\big/{\mathrm{SL}_2(\mathbb{Z})}$.

3. Set $G = \left\{ \begin{bmatrix} 1 & x & z \\ 0 & 1 & y \\ 0 & 0 & 1 \end{bmatrix} \mid x, y, z \in \mathbb{R} \right\}$ and $\Gamma = \left\{ \begin{bmatrix} 1 & a & c \\ & 1 & b \\ & & 1 \end{bmatrix} \mid a, b, c \in \mathbb{R} \right\}$. Then Γ is a discrete subgroup of G, and $G \twoheadrightarrow {G}\big/{\Gamma}$ is a covering projection. We call ${G}\big/{\Gamma}$ an *Iwasawa manifold*. Since G is simply connected, we also have that $\pi_1({G}\big/{\Gamma}) \cong \Gamma$.

Exercise 2. $\pi_1(X \times Y, (x_0, y_0)) \cong \pi_1(X, x_0) \times \pi_1(Y, y_0)$.

Lemma 8. Let $F : Z \times I \to X$ be any map and $p : Y \to X$ be a covering projection. Suppose that there is some $\widetilde{F}_0 : Z \times \{0\} \to Y$ such that $p \circ \widetilde{F}_0 = F_0$. Then there exists a unique map $\widetilde{F} : Z \times I \to Y$ such that $p \circ \widetilde{F} = F$ and $\widetilde{F} \restriction_{Z \times \{0\}} = \widetilde{F}_0$.

Corollary 1. (Path lifting property)

1. If $\gamma : I \to X$ is a path and $y_0 \in Y$ with $p(y_0) = \gamma(0)$, then there exists a unique $\tilde{\gamma} : I \to Y$ such that $\tilde{\gamma}(0) = y_0$ and $p \circ \tilde{\gamma} = \gamma$.

2. Let γ_0, γ_1 be two paths in X and let $H : \gamma_0 \simeq_p \gamma_1$. Let $\tilde{\gamma}_0$ and $\tilde{\gamma}_1$ be respective lifts such that $\tilde{\gamma}_0(0) = \tilde{\gamma}_1(0)$. Then there exists a unique $\widetilde{H} : \tilde{\gamma}_0 \simeq_p \tilde{\gamma}_1$ such that $p \circ \widetilde{H} = H$.

Proof.

1. Let $Z = *$

2. Let $Z = I$.

$\square$

Theorem 3. $\pi_1(S^1, 1) \cong \mathbb{Z}$.

Proof. Let γ be a path in S^1 based at 1. We have a covering map $p : \mathbb{R} \to S^1$ given by $t \mapsto e^{2\pi i t}$. By our last corollary, there is some unique lift $\tilde{\gamma}$ of γ such that $\tilde{\gamma}(0) = 0$ and $p \circ \tilde{\gamma} = \gamma$. Since $p^{-1}(1) = \mathbb{Z}$, our last corollary gives a function $\psi : \pi_1(S^1, 1) \to \mathbb{Z}$ given by $[\gamma] \mapsto \tilde{\gamma}(1)$. Since $\mathbb{R}$ is simply connected, we have that ψ is bijective. It remains to verify that it's a homomorphism. Let $[f], [g] \in \pi_1(S^1, 1)$ and take their respective unique lifting $\tilde{f}$ and $\tilde{g}$. Write $n = \tilde{f}(1)$ and $m = \tilde{g}(1)$. Define the path $\tilde{\tilde{g}}(s) = n + \tilde{g}(s)$ in $\mathbb{R}$, which begins at n. Since $p(n + x) = p(x)$ for every $x \in \mathbb{R}$, we see that $\tilde{\tilde{g}}$ lifts g. Then $\tilde{f} * \tilde{\tilde{g}}$ lifts $f * g$ and ends at the point $n + m$. Hence $\psi([f] * [g]) = n + m = \psi([f]) + \psi([g])$, as required. $\square$

Corollary 2. There is no retraction of D^2 onto S^1.

Proof. Suppose, for contradiction, that there is some retraction r. Then we get an induced sequence of group maps

$$\pi_1(S^1, 1) \xrightarrow{\ i_* \ } \pi_1(D^2, 1) \xrightarrow{\ r_* \ } \pi_1(S^1, 1) \ .$$

But $r_* \circ i_* = (r \circ i)_* = (\mathbb{1}_{S^1})_* = \mathbb{1}_{\pi_1(S^1)}$. Thus, r_* is surjective, which is impossible. $\square$

Corollary 3. (Brouwer fixed point theorem in dimension 2) If $\varphi : D^2 \to D^2$ is any map, then $\varphi(x_0) = x_0$ for some $x_0 \in D^2$.

Proof. If not, then we may define a retraction r of D^2 onto S^1 as follows. For each $x \in D^2$, set $r(x)$ equal to the point on the circle that intersects the ray from $h(x)$ to x. $\square$

2.1 Lecture 5

We give a proof of a result that we've already used.

Lemma 9. (Homotopy lifting property) Let $F : Z \times I \to X$ be any map and $p : Y \to X$ be a covering projection. Suppose that there is some $\widetilde{F}_0 : Z \times \{0\} \to Y$ such that $p \circ \widetilde{F}_0 = F_0$. Then there exists a unique map $\widetilde{F} : Z \times I \to Y$ such that $p \circ \widetilde{F} = F$ and $\widetilde{F} \upharpoonright_{Z \times \{0\}} = \widetilde{F}_0$.

Proof. Let $z_0 \in Z$.

Claim 1. There exist a neighborhood $U_{z_0} \subset Z$ and a lift $\widetilde{F}$ of $F \upharpoonright_{U_{z_0} \times I}$ such that $p \circ \widetilde{F} = F$ on $U_{z_0} \times I$.

Proof. For any $(z_0, t) \in Z \times I$, note that $F(z_0, t)$ has some neighborhood $V_{z_0,t}$ such that

$$p^{-1}(V_{z_0,t}) = \coprod_\alpha V_{z_0,t,\alpha}$$

with $p : V_{z_0,t,\alpha} \to V_{z_0,t}$ a homeomorphism. Thus, $F^{-1}(V_{z_0,t})$ contains some set of the form $\underbrace{U_{z_0,t}}_{\text{nbhd of } z_0} \times (a_t, b_t)$,

so that $F(U_{z_0,t} \times (a_t, b_t)) \subset V_{z_0,t}$. This makes $\{(a_t, b_t)\}_{t \in I}$ an open cover of I. As I is compact, there is some $k \in \mathbb{N}$ such that $\{(a_{t_i}, b_{t_i})\}_{i=1,\dots,k}$ cover I. Set $U_{z_0} = \bigcap_{1 \le i \le k} U_{z_0,t_i}$, which must be open and contain z_0. We obtain a sequence $0 = t_0 < t_1 < \cdots < t_n = 1$ such that $F(U_{z_0} \times [t_i, t_{i+1}])$ is contained in an evenly covered set of X. Now, $\widetilde{F}_0$ is contained in some unique sheet of $p^{-1}(U_{z_0,0}) = \coprod_j \widetilde{U}_{z_0,0,j} \subset Y$, say, j_0. Define $\widetilde{F} : U_{z_0} \times [0, t_1] \to \widetilde{U}_{z_0,0,j_0}$ as the composite $p_{j_0}^{-1} \circ F \upharpoonright_{U_{z_0} \times [0,t_1]}$ where $p_{j_0} : \widetilde{U}_{z_0,0,j_0} \to U_{z_0,0}$ is some homeomorphism.

Suppose that we have extended $\widetilde{F}$ to $U_{z_0} \times [0, t_i]$. We can use a similar argument to define an extension $\widetilde{F}$ on $U_{z_0} \times [t_i, t_{i+1}]$. By induction, it follows that we can construct a lift $\tilde{F} : U_{z_0} \times I \to Y$ of F.

It remains to verify that such a lift is unique. For now, assume that $Z = *$. Suppose that $\widetilde{F}$ and $\widetilde{F}'$ are two lifts of $F : I \to X$ such that $\widetilde{F}(0) = \widetilde{F}'(0)$. Assume inductively that $\tilde{F} = \widetilde{F}'$ on $[0, t_i]$. Since both $\widetilde{F}([t_i, t_{i+1}])$ and $\widetilde{F}'([t_i, t_{i+1}])$ are connected and $\widetilde{F}(t_i) = \widetilde{F}'(t_i)$, there is a single sheet over U_{i-1} in which both $\widetilde{F}([t_i, t_{i+1}])$ and $\widetilde{F}'([t_i, t_{i+1}])$ are contained. Since p is injective on this sheet and $p \circ \widetilde{F} = p \circ \widetilde{F}'$, it follows that $\widetilde{F} = \widetilde{F}'$ on $[t_i, t_{i+1}]$. We are done with our induction.

As a result, the lifts $\{F \upharpoonright_{U_z \times [0,t_1]}\}_{z \in Z}$ constructed above must agree with each other when $U_z \cap U_{z'} \ne \emptyset$. We may thus apply the gluing lemma to get a lift $\tilde{F} : Z \times I \to Y$ of F. This must be unique as it is unique when restricted to each segment $\{z\} \times I$. $\qquad\square$

$\square$

Corollary 4. Let $p : (Y, y_0) \to (X, x_0)$ be a covering map. Then $p_* : \pi_1(Y, y_0) \to \pi_1(X, x_0)$ is injective.

Proof. Let $[\gamma] \in \ker p_*$, so that $[p \circ \gamma] = [c_{x_0}]$. By the path lifting property, there must be some homotopy $\gamma \simeq_p c_{y_0}$. Thus, $[\gamma] = 0$. $\qquad\square$

Theorem 4. (Fundamental theorem of algebra) Any nonconstant $p(x) \in \mathbb{C}[x]$ has a root.

Proof. We may assume that $p(x)$ is monic. Write $p(x) = z^n + a_1 z^{n-1} + \cdots + a_n$. Suppose that $p(x)$ has no roots. Then $p : \mathbb{C} \to \mathbb{C}^\times \simeq S^1$. For each real number $r \ge 0$, define the loop $f_r : I \to (S^1, 1)$ by

$$f_r(s) = \frac{p(re^{2\pi i s})/p(r)}{|p(re^{2\pi i s})/p(r)|}.$$

Note that $(f_r)_{r \geq 0}$ determines a path homotopy from the trivial loop, so that $f_r \simeq_p c_1$ for each r. Set $r' > 1 + |a_1| + \cdots + |a_n|$. If $|z| = r'$, then

$$
\begin{aligned}
|z|^n &> (|a_1| + \cdots + |a_n|)|z|^{n-1} \\
&\geq |a_1 z^{n-1}| + |a_2| + \cdots + |a_n| \\
&\geq |a_1 z^{n-1} + a_2 + \cdots + a_n|.
\end{aligned}
$$

This implies that if $0 \leq t \leq 1$, then $p_t(x) = z^n + t(a_1 z^{n-1} + a_2 + \cdots + a_n)$ is nonzero on the circle $|z| = r'$. Then the map

$$
(s, t) \mapsto \frac{p_t(r' e^{2\pi i s})/p_t(r')}{|p_t(r' e^{2\pi i s})/p_t(r')|}
$$

is a homotopy $e^{2\pi i n s} \simeq_p f_{r'}$. Hence $[1]^n = [e^{2\pi i n s}] = 0$. Since $\pi_1(S^1, 1) \cong \mathbb{Z}$, this makes $n = 0$. Therefore, $p(x)$ must be constant. $\qquad\square$

Remark 6. Let $\{G_\alpha\}$ be any collection of objects of **Grp**. Recall that the *free product* $*_\alpha G_\alpha$ *of the* G_α is the unique object satisfying the following universal property. For any collection of maps $(\varphi_\alpha : G_\alpha \to H)$ where H is a group, there exists a unique map $*\varphi_\alpha$ such that

$$
\begin{array}{ccc}
*G_\alpha & \xrightarrow{\ *\varphi_\alpha\ } & H \\
\uparrow & \nearrow_{\varphi_\alpha} & \\
G_\alpha & &
\end{array}
$$

commutes for each α.

Note 8. This is exactly the coproduct in **Grp**, which always exists.

Theorem 5. (van Kampen) Write the space X as the union $\bigcup_{\alpha \in A} A_\alpha$ of path connected open subsets A_α. Assume that each A_α is path connected and that each $A_\alpha \cap A_\beta$ is path connected. Then

$$
\Phi : *_\alpha \pi_1(A_\alpha) \to \pi_1(X)
$$

is surjective. Moreover, if each $A_\alpha \cap A_\beta \cap A_\delta$ is path connected, then $\ker \Phi$ is precisely the normal subgroup N generated by every element of the form

$$
i_{\alpha\beta}(\gamma) i_{\beta\alpha}(\gamma^{-1}), \quad \gamma \in \pi_1(A_\alpha \cap A_\beta)
$$

where $i_{\alpha\beta} : \pi_1(A_\alpha \cap A_\beta) \to \pi_1(A_\alpha)$ denotes the map induced by inclusion. In this case, $\pi_1(X) \cong *_\alpha G_\alpha / N$ where $G_\alpha := \pi_1(A_\alpha)$. .

Remark 7. Equivalently, van Kampen says that functor $\pi_1(-) : \textbf{Top} \to \textbf{Grp}$ respects fibered coproducts (also known as *amalgamated free products*).

Corollary 5. If $X = A \cup B$ where A and B are open in X and $\pi_0(A) = \pi_0(B) = \pi_0(A \cap B) = 0$, then

$$
\pi_1(X) \cong \pi_1(A) \underset{\pi_1(A \cap B)}{*} \pi_1(B).
$$

Corollary 6. Let $X = A \cup B$ such that both A and B are closed in X and path connected. Suppose that $\pi_0(A \cap B) = 0$. Further, suppose that $A \cap B$ is a deformation retract both of some open set U in A and of some open set V in B. Then $\pi_1(X) \cong \pi_1(A) \underset{\pi_1(A \cap B)}{*} \pi_1(B)$.

Proof. Note that $U \setminus \underbrace{(A \cap B)}_{=U \cap V}$ and $V \setminus (A \cap B)$ are open in $U \cup V$. Therefore, we may patch the given deformation retractions onto $A \cap B$ together to get a deformation retraction of $U \cup V$ onto $A \cap B$. Similarly, we can patch together our given deformation retractions with $\mathbb{1}_A$ and $\mathbb{1}_B$ to get deformation retractions of

13

$A \cup V$ onto A and of $B \cup U$ onto B, respectively. This induces an isomorphism of diagrams (in particular, spans).

$$\begin{array}{ccccc} \pi_1(A) & \longleftarrow & \pi_1(A \cap B) & \longrightarrow & \pi_1(B) \\ \Big\downarrow{\cong} & & \Big\downarrow{\cong} & & \Big\downarrow{\cong} \\ \pi_1(A \cup V) & \longleftarrow & \pi_1(U \cup V) & \longrightarrow & \pi_1(B \cup U) \end{array}$$

As a result, their pushouts (i.e., colimits) must be isomorphic.

Now, note that $(A \cup V)^c = B \setminus V$, which is closed in X. Likewise, $(B \cup U)^c$ is closed in X. We can apply van Kampen to get

$$\pi_1(X) \cong \pi_1(A \cup V) \underset{\pi_1(U \cup V)}{*} \pi_1(B \cup U).$$

By our argument above, this implies that

$$\pi_1(X) \cong \pi_1(A) \underset{\pi_1(A \cap B)}{*} \pi_1(B).$$

$\square$

Example 15.

1. Let A and B denote the two circles forming the wedge sum $S_1 \vee S_1$. Note that $A \cap B = *$, so that $N = *$. Thus, $\pi_1(S_1 \vee S_1) \cong \mathbb{Z} * \mathbb{Z}$.

2. Recall that $\mathbb{RP}^2 \cong {D^2}/{\sim}$ where $x \sim -x$ when $x \in S^1$. Decompose ${D^2}/{\sim}$ into a small disk A around the origin and an annulus B so that $A \cap B$ is a smaller annulus bounded above by the boundary of A and below by the inner boundary of B. Then $\pi_1(A) = 0$, and $\pi_1(B) \cong \pi_1(\mathbb{RP}^1) \cong \mathbb{Z} \cong \pi_1(A \cap B)$. Write $\pi_{(}B) = \langle b \rangle$ and $\pi_1(A \cap B) = \langle \gamma \rangle$. Then $i_{AB}(\gamma) = 0$. Also, $i_{BA}(\gamma) = b^2$, as shown below.
Figure 4: copied from *https://www.math3ma.com*

By van Kampen, it follows that $\pi_1(\mathbb{RP}^2) \cong \pi_1(A) \underset{\pi_1(A \cap B)}{*} \pi_1(B) \cong {\langle b \rangle}/{\langle b^2 \rangle} \cong \mathbb{Z}/2\mathbb{Z}$.

2.2 Lecture 6

Definition. A *knot* is a piecewise smooth embedding of S^1 into $\mathbb{R}^3$. Two knots K_1 and K_2 are *equivalent* if there is some homeomorphism $\varphi : \mathbb{R}^3 \to \mathbb{R}^3$ such that $\varphi(K_1) = K_2$.

Example 16.

1. The *unknot* is the standard embedding $S^1 \hookrightarrow \mathbb{R}^3$.

2. The following space is called the *trefoil knot*.
Lemma 10. The *knot group* $\pi_1(\mathbb{R}^3 \setminus K)$ is isomorphic to $\pi_1(S^3 \setminus K)$.

Proof. Recall that $S^3 \cong \mathbb{R}^3 \cup \{\infty\}$. Write $S^3 \setminus K$ as the union of $\mathbb{R}^3 \setminus K$ and the open ball $B := (\mathbb{R}^3 \setminus D) \cup \{\infty\}$ where $D \supset K$ is a sufficiently large disk. Then both $B \cap (\mathbb{R}^3 \setminus K)$ and B are simply connected (the former being homeomorphic to $S^2 \times \mathbb{R}$). By van Kampen, $\pi_1(S^3 \setminus K) \cong \pi_1(\mathbb{R}^3 \setminus K)$. $\qquad\square$

Note 9. We have that $S^3 \cong ST_1 \cup_T ST_2$ where ST_1 and ST_2 denote solid tori with common boundary a torus. Indeed,

$$S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 = 1\}$$

$$ST_1 = \{(z_1, z_2) \in S^3 \mid |z_1|^2 \leq \tfrac{1}{2}\} \cong D^2 \times S^1$$

$$ST_1 = \{(z_1, z_2) \in S^3 \mid |z_2|^2 \leq \tfrac{1}{2}\} \cong S^1 \times D^2$$

$$ST_1 \cap ST_2 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 = |z_2|^2 = \tfrac{1}{2}\} \cong S^1 \times S^1.$$

Definition. Let M^n be a manifold. A *foliation of M* is a collection $\{\mathscr{L}_\alpha\}_{\alpha \in A}$ of immersed submanifolds of fixed dimension l, called *leaves*, such that $M = \coprod_{\alpha \in A} \mathscr{L}_\alpha$ and for each $p \in M$, there is some smooth chart (U, φ) around p with $\varphi(\mathscr{L}_\alpha \cap U) \subset \mathbb{R}^l$ for each α.

Example 17.

1. The collection of circles $\{\{q\} \times S^1\}_{q \in S^1}$ forms a foliation of the torus.

2. For each $\theta \in \mathbb{R}$, define the curve in the torus $\gamma_\theta(t) = (e^{it}, e^{i(\alpha t + \theta)})$. Then the collection of curves $\{\operatorname{im} \gamma_\theta\}_{\theta \in \mathbb{R}}$ forms another foliation of the torus. If $\theta \in \mathbb{Q}$, then each curve is an embedded circle. Otherwise, it is dense in the torus.

Theorem 6. The torus is the only surface that admits a foliation.

Remark 8. The so-called Reeb torus demonstrates that there are foliations on S^3.

Remark 9. If $M = \coprod_\alpha \mathscr{L}_\alpha$, then $\mathscr{L} := \bigcup_{x \in M} T_x \mathscr{L}_{\alpha_x}$ (where $x \in L_{\alpha_x}$) is a subbundle of TM such that $X, Y \in C^\infty(M, \mathscr{L}) \implies [X, Y] \in \mathscr{L}$. Frobenius states the converse of this.

Note 10. (Wirtinger presentation) Draw our knot K as follows. Take a finitely many arcs $\alpha_1, \ldots, \alpha_n$ such that each α_i is connected to $\alpha_{i+1} \mod n$. Orient the knot so that the arcs are labeled in the direction of the orientation. Draw a short arrow x_i passing under each α_i from right to left. The x_i represent loops starting at a base point going under the arc from its base to head and back to base. At each crossing, we get a relation among the x_i as follows.
For each i, let r_i denote the relation $x_k x_i = x_{i+1} x_k$.

Proposition 10. $\pi_1(S^3 \setminus \text{unknot}) \cong \mathbb{Z}$.

15

Theorem 7. $\pi_1(\mathbb{R}^3 \setminus K, *) \cong \langle x_1, \ldots, x_n \mid r_1, \ldots, r_n \rangle$.

Proof. We may embed each arc α_i in the plane $z = 0$ except for a small vertical segment at each end of the arc, which will lie instead in the plane $z = -1$.

Let $A = \{z \geq 1\} \setminus K$. The lower boundary of A is the union of the n line segments with each β_i removed. For each i $1 \leq i \leq n$, let B_i equal the union of a solid rectangular box whose top lies on $z = -1$ surrounding but excluding β_i and an arc connection β_i to $*$. Make the B_i disjoint. Let C equal the closure of everything below the B_i. Then we can write

$$\mathbb{R}^3 \setminus K = A \cup B_1 \cup \cdots \cup B_n \cup C.$$

We see that $\pi_1(A, *) \cong \mathbb{F}_n$, $\pi_1(B_1) = 0$, and C is contractible. Now, $A \cap B_1$ equals a rectangle minus β_1 together with an arc connecting β_1 to $*$. Thus, $A \cap B_1 \simeq S^1$. Write $\pi_1(A \cap B_1) = \langle \gamma_1 \rangle \cong \mathbb{Z}$. But $i_{AB_1}(\gamma) = x_1 x_k^{-1} x_2^{-1} x_k$. By van Kampen, we get $\pi_1(A \cup B_1) \cong \mathbb{F}_n / (r_1)$. By induction, it follows that

$$\pi_1(A \cup B_1 \cup \cdots \cup B_n) \cong \mathbb{F}_n / (r_1, \ldots, r_n).$$

Finally, since C is contractible, we get $\pi_1(A \cup B_1 \cup \cdots \cup B_n \cup C) \cong \pi_1(A \cup B_1 \cup \cdots \cup B_n)$. $\qquad \square$

2.3   Lecture 7

Remark 10. If $G = \langle g_1, \ldots, g_n \mid w_1, \ldots, w_m \rangle$, then $G \cong \mathbb{F}(g_1, \ldots, g_n) / N$ where N denotes the normal subgroup generated by $w_1, \ldots, w_m$ and each w_i is a word in $g_1, \ldots, g_n$. Now, let $G_1 = \langle g_1, \ldots, g_n \mid w_1, \ldots, w_m \rangle$ and $G_2 = \langle h_1, \ldots, h_k \mid u_1, \ldots, u_l \rangle$ It is known that the following two problems are undecidable.

(a) (isomorphism problem) Is $G_1 \cong G_2$?

(b) (word problem) Given a word w over $\{g_1, \ldots, g_n\}$, is $w = e$?

Example 18. Let S_g denote the (closed) orientable surface of genus g. Note that $S_g \cong S_{g-1} \# T$. We can draw S_g as an oriented $4g$-gon with pairs of sides identified as follows.

Figure 5: copied from the Manifold Atlas

For example, $a_1 \sim \bar{a}_1$. Then we can decompose S_g into a small disk A around the origin and an annulus-like space B so that $A \cap B$ is a smaller annulus bounded above by the boundary of A and below by the inner boundary of B. Then $\pi_1(A \cap B) \cong \langle \gamma \rangle$ where $|\gamma| = \infty$. Further, $\pi_1(A) = 0$, and $\pi_1(B) \cong \underset{\{1,2,\ldots,2g\}}{*} \mathbb{Z}$ since B deformation retracts onto a bouquet of $2g$ circles. Observe that $i_{BA}(\gamma) = \prod_{i=1}^{g}[a_i, b_i]$, which implies that

$$\pi_1(S_g) \cong \Big\langle a_1, \ldots, a_g, b_1, \ldots, b_g \mid \prod_{i=1}^{g}[a_i, b_i] = 1 \Big\rangle.$$

Note 11. The comb space is path connected but not locally path connected.

Lemma 11. If $p : (Y, y_0) \to (X, x_0)$ is a covering map, then there is an isomorphism of sets

$$p^{-1}(x_0) \xrightarrow{\cong} \pi_1(X, x_0)\big/ p_* \pi_1(Y, y_0).$$

Proof. Let γ be a loop in (X, x_0). Lift it to $\tilde{\gamma}$ such that $\tilde{\gamma}(0) = y_0$. Set $\alpha(\gamma) = \tilde{\gamma}(1) \in p^{-1}(x_0)$. The map $\alpha : \pi_1(X, x_0)\big/ p_* \pi_1(Y, y_0) \to p^{-1}(x_0)$ is well-defined since $\widetilde{h * \gamma} = \tilde{h} * \tilde{\gamma}$ when $[h] \in p_* \pi_1(Y, y_0)$. It is surjective because Y is path connected. If $\alpha(\gamma_1) = \alpha(\gamma_2)$, then $\tilde{\gamma}_1 * \tilde{\gamma}_2^{-1} = \widetilde{\gamma_1 * \gamma_2^{-1}}$ is a loop in (Y, y_0), so that $\gamma_1 * \gamma_2^{-1} \in p_* \pi_1(Y, y_0)$. This shows that α is injective as well. $\square$

Lemma 12. (Lifting criterion) Let $p : (Y, y_0) \to (X, x_0)$ be a covering map and $f : (Z, z_0) \to (X, x_0)$ a map with Z path connected and locally path connected. Then there exists some map $\tilde{f}$ fitting into the commutative diagram

$$
\begin{array}{ccc}
 & & Y \\
 & \overset{\tilde{f}}{\nearrow} & \downarrow{\scriptstyle p} \\
Z & \xrightarrow{\ f\ } & X
\end{array}
$$

if and only if $f_* \pi_1(Z, z_0) \subset p_* \pi_1(Y, y_0) \subset \pi_1(X, x_0)$.

Proof.
($\Longrightarrow$) Note that $f_* = (p\tilde{f})_* = p_* \tilde{f}_*$.

($\Longleftarrow$) Let $z \in Z$. Find some path $\gamma : z_0 \rightsquigarrow z$. Then $f\gamma$ is a path in X starting at x_0. There exists a unique lift $\widetilde{f\gamma}$ starting at y_0. Set $\tilde{f}(z) = \widetilde{f\gamma}(1)$. We must check that $\tilde{f}$ is well-defined. Let $\gamma' : z_0 \rightsquigarrow z$. Then $h_0 := (f\gamma') * (f\gamma)^{-1}$ is a loop at x_0. Note that $[h_0] \in f_* \pi_1(Z, z_0) \subset p_* \pi_1(Y, y_0)$. Hence there is some homotopy $H : h_0 \simeq_p p \circ \tilde{h}_1$ for some loop $\tilde{h}_1$ at y_0. Apply the homotopy lifting property to get a homotopy $\widetilde{H} : \tilde{h}_0 \simeq_p \tilde{h}_1$, so that $\tilde{h}_0$ is a loop. By uniqueness of lifts, $\tilde{h}_0 = \widetilde{f\gamma'} * \widetilde{f\gamma}^{-1}$, which implies that $\widetilde{f\gamma'}(1) = \widetilde{f\gamma}(1-0) = \widetilde{f\gamma}(1)$, as required.

It remains to verify that $\tilde{f}$ is continuous. Find some path $\lambda : z_0 \rightsquigarrow z$. We know that there is some neighborhood $U \ni f(z)$ that is is evenly covered by p. Let $\widetilde{U}$ denote the sheet containing $\tilde{f}(z)$ and find some homeomorphism $p : \widetilde{U} \to U$. Find some path connected neighborhood $V \ni z$ such that $f(Z) \subset U$. Let $z' \in V$. Find some path $\eta : z \rightsquigarrow z'$. Then the path $(f\lambda) * (f\eta)$ lifts to $(\widetilde{f\lambda}) * (\widetilde{f\eta})$ where $\widetilde{f\eta} = p^{-1} f\eta$. As z' was arbitrary in V, this implies that $\tilde{f} \upharpoonright_V = p^{-1} f \upharpoonright_V$, which is continuous. Hence $\tilde{f}$ is continuous as well. $\square$

Proposition 11. (Unique lifting property) Let $p : Y \to X$ be a covering map and $f : Z \to X$ a map with $\tilde{f}_1, \tilde{f}_2 : Z \to Y$ lifts of f. Let Z be connected. If there is some $z_0 \in Z$ such that $\tilde{f}_1(z_0) = \tilde{f}_2(z_0)$, then $\tilde{f}_1 = \tilde{f}_2$.

Remark 11. Let X be a space with $\pi_0(X) = 0$. When is there a locally path connected covering space $p : \widetilde{X} \to X$ such that $\pi_1(\widetilde{X}) = 0$. Suppose that such a space exists. Let $x \in X$. Suppose that the open set $U \subset X$ with $x \in U$ is evenly covered. Ley $\widetilde{U} \subset \widetilde{X}$ be one sheet. If γ is a loop in U, then it lifts to a loop $\tilde{\gamma}$ at, say, $y \in \widetilde{U}$, which must be nullhomotopic. Find some homotopy $H : \tilde{\gamma} \simeq_p c_y$. Then $pH : \gamma \simeq_p c_x$. Therefore, for any $x \in X$, there is some neighborhood $U \ni x$ such that $\pi_1(U) = 0$.

Definition. Such a property of X is called being *semilocally simply connected.*

Theorem 8. Suppose that X is path connected, locally path connected, and semilocally simply connected (hereafter "swell"). Then there is some covering map $p : \widetilde{X} \to X$ such that $\widetilde{X}$ is simply connected.

Proof. Pick $x_0 \in X$. Let $P_{x_0} := \{\gamma : I \to X \mid \gamma(0) = x_0\}$. Set $\widetilde{X} = {P_{x_0}}/{\simeq_p}$, endowed with the compact-open topology. $\square$

Lemma 13. Let X be a swell space. If $Y_1, Y_2 \xrightarrow{p_1, p_2} X$ are two simply connected covering spaces, then they are *isomorphic* in the following sense. There is some homeomorphism $\psi : Y_2 \to Y_1$ such that

$$
\begin{array}{ccc}
Y_1 & \xleftarrow{\psi} & Y_2 \\
{\scriptstyle p_1}\downarrow & \swarrow {\scriptstyle p_2} & \\
X & &
\end{array}
$$

commutes (i.e., ψ is a bundle isomorphism).

Proof. By the lifting criterion, we can obtain lifts

$$
\begin{array}{ccc}
 & & Y_2 \\
 & {\scriptstyle \tilde{p}_1}\nearrow & \downarrow {\scriptstyle p_2} \\
Y_1 & \xrightarrow{p_1} & X
\end{array}
$$

.

$$
\begin{array}{ccc}
 & & Y_1 \\
 & {\scriptstyle \tilde{p}_2}\nearrow & \downarrow {\scriptstyle p_1} \\
Y_2 & \xrightarrow{p_2} & X
\end{array}
$$

Then $\tilde{p}_2\tilde{p}_1 = \mathbb{1}_{Y_1}$ since p_1 has a unique lift. Similarly, $\tilde{p}_1\tilde{p}_2 = \mathbb{1}_{Y_2}$. Hence $\tilde{p}_2 : Y_2 \xrightarrow{\cong} Y_1$. $\square$

2.4 Lecture 8

Definition. If X is a swell space, then we call such a cover $p : (\widetilde{X}, \tilde{x}_0) \to (X, x_0)$ the *universal cover of* X. It is universal in that for any path connected covering space $p' : (Y, y_0) \to (X, x_0)$, there exists a unique covering map $p'' : (\widetilde{X}, \tilde{x}_0) \to (Y, y_0)$ such that $p''p' = p$.

Lemma 14. Let X be swell. For any subgroup $H \leq \pi_1(X, x_0)$, there exists a path connected covering space $p_H : X_H \to X$ such that $p_H(\pi_1(X_H, h_H)) = H$.

Proof. Define an equivalence relation $\sim$ on the universal cover $p : \widetilde{X} \to X$ as follows. Let $y_1 \sim y_2$ if $p(y_1) = p(y_2)$ and for any two paths γ_1 and γ_2 from x_0 to y_1 and y_2, respectively, $(p\gamma_1) * (p\gamma_2)^{-1} \in H$. Set $X_H = {\widetilde{X}}/{\sim}$ and note that the map $p_H : X_H \to X$ given by $[y] \mapsto p(y)$ is a covering space. Set $x_H = q(\tilde{x}_0)$ where $q : \widetilde{X} \to X_H$ denotes the natural projection. We know that $p_H\pi_1(X_H, x_H)$ consists of loops γ in (X, x_0) whose lifts to X_H are also loops. If $\tilde{\gamma}$ denotes the lift of γ to $\widetilde{X}$, then we see that

$$
\tilde{\gamma}(1) \sim \tilde{x}_0 \iff p_H(\tilde{\gamma}^{-1} c_{\tilde{x}_0}) \in H,
$$

meaning that $p_H \circ \tilde{\gamma}$ is a loop at x_0 if and only if γ belongs to H. $\square$

Lemma 15. Let X be path connected and locally path connected. Suppose that $p_1 : (Y_1, y_1) \to (X, x_0)$ and $p_2 : (Y_2, y_2) \to (X, x_0)$ are two (path connected) covering maps. Then there exists an isomorphism $\varphi : (Y_1, y_1) \to (Y_2, y_2)$ if and only if $p_{1*}\pi_1(Y_1, y_1) = p_{2*}\pi_1(Y_2, y_2)$.

Proof. The ($\Longrightarrow$) direction follows from the fact that $p_1 = p_2 f$ and $p_2 = p_1 f^{-1}$.

($\Longleftarrow$) Apply the lifting criterion twice to lifts $\tilde{p}_1$ and $\tilde{p}_2$ such that $p_2\tilde{p}_1 = p_1$ and $p_1\tilde{p}_2 = p_2$. By the unique lifting property, $\tilde{p}_1\tilde{p}_2 = \mathbb{1}$ and $\tilde{p}_2\tilde{p}_1 = \mathbb{1}$. Hence $\tilde{p}_1$ and $\tilde{p}_2$ are inverse isomorphisms. $\quad\square$

Corollary 7. Let X be swell. There is a bijection between the set of isomorphism classes of path connected covering spaces $p : (Y, y) \to (X, x_0)$ of X and the set of subgroups of $\pi_1(X, x_0)$ given by

$$(Y, y) \longleftrightarrow p_*\pi_1(Y, y).$$

Definition. Let $p : \widetilde{X} \to X$ be a covering space. The set of isomorphisms $\widetilde{X} \to \widetilde{X}$, called *deck transformations*, forms a group $G(\widetilde{X})$ under composition.

Remark 12. This corresponds to the Galois group.

Note 12. By the unique lifting property, if $\widetilde{X}$ is path connected, then any $f \in G(\widetilde{X})$ is entirely determined by its value at a single point.

Definition. A covering space $p : Y \to X$ is *normal* if $G(Y)$ acts transitively on the set $p^{-1}(x)$ for each $x \in X$.

Lemma 16. Let $p : (Y, y_0) \to (X, x_0)$ be a path connected covering space with X swell. Let $H := p_*\pi_1(Y, y_0)$. Then

1. p is normal if and only if $H \trianglelefteq \pi_1(X, x_0)$.

2. $G(Y) \cong {N(H)}\big/{H}$.

Hence $G(Y) \cong {\pi_1(X, x_0)}\big/{H}$ when p is normal.

Proof.

1. For any $y_1 \in p^{-1}(x_0)$, there is some path $\eta : y_0 \rightsquigarrow y_1$. Then $\pi_1(Y, y_0) \cong \pi_1(Y, y_1)$ via the map $[\gamma] \mapsto \eta^{-1}\gamma\eta$. Note that $p\eta \in \pi_1(X, x_0)$ and that $p_*\pi_1(Y, y_0) = [p\eta]p_*\pi_1(Y, y_1)[p\eta]^{-1}$. Hence $[\gamma] \in N(H) \iff p_*\pi_1(Y, y_0) = p_*\pi_1(Y, y_1)$ where γ lifts to a path $y_0 \rightsquigarrow y_1$. By the lifting criterion together with the unique lifting property, it follows that $[\gamma] \in N(H)$ if and only if there is some deck transformation $Y \to Y$ mapping y_0 to y_1. Hence $N(H) = \pi_1(X, x_0)$ if and only if p is normal.

2. Define $\varphi : N(H) \to G(Y)$ by mapping $[\gamma]$ to the deck transformation sending y_0 to y_1. The preceding argument shows that φ is surjective. Further, $\ker \varphi$ consists of loop at x_0 whose lifts are loops in Y. Thus, $\ker \varphi = H$.

$\quad\square$

Example 19. If Γ acts freely and properly discontinuously on the space Y, then the quotient map $Y \to {Y}\big/{\Gamma}$ is a normal covering space such that $\Gamma \cong G(Y)$. Hence $\Gamma \cong {\pi_1(X, x_0)}\big/{p_*\pi_1(Y, y_0)}$ where $X := {Y}\big/{\Gamma}$.

Definition. A *graph* is a 1-dimensional CW-complex.

Lemma 17. Let G be a graph. Then $\pi_1(G)$ is a free group.

Proof. Since every tree is contractible, we see that G is homotopy equivalent to a wedge sum of circles by noting that $\bigvee_\alpha S^1_\alpha \simeq {G}\big/{T} \simeq G$ where T is a maximal tree contained in G. $\quad\square$

Note 13. If X is a graph and $p : Y \to X$ is a covering space, then Y is also a graph.

Theorem 9. Let Γ be a free group and $H \leq \Gamma$. Then H is free.

Proof. We have that $\Gamma \cong \pi_1(X)$ where $X := \bigvee_\alpha S^1_\alpha$. Also, H corresponds to some covering space $p : Y \to X$. Therefore, Y is a graph, and $\pi_1(Y)$ is free. This implies that $H = p_*\pi_1(Y)$ is free since p_* is injective. $\quad\square$

3 Homology

Definition.

1. The *standard k-simplex* is the set

$$\Delta^k = \{(t_0, \ldots, t_k) \mid \sum t_i = 1, \ t_i \geq 0\} = \{(x_1, \ldots, x_n) \mid 0 \leq x_1 \leq x_2 \leq \cdots \leq x_k \leq 1\}.$$

2. For each $i = 0, \ldots, k+1$, define the *face map* $\partial^i : \Delta^k \to \Delta^{k+1}$ by $(t_0, \ldots, t_k) \mapsto (t_0, \ldots, t_{i-1}, 0, t_i, \ldots, t_k)$.

3. An *(abstract) simplicial complex* is a set K together with a collection of finite subsets $\Sigma \subset P(K)$ such that if $\sigma \in \Sigma$ and $\tau \subset \sigma$, then $\tau \in \Sigma$. If $\sigma \in \Sigma$ and $|\sigma| = k$, then σ is called a $(k-1)$-*simplex*. Any subset of a simplex is called a *face*.

4. An *ordered simplex* is a simplex equipped with an ordering of its vertices.

Definition. Let (K, Σ) be a simplicial complex. Let S denote the set of ordered k-simplices in K. Define

$$C_k(K, \Sigma) = \bigoplus_{s \in S} \mathbb{Z} \big/ {\sim}$$

where $v_0 \cdots v_k \sim (-1)^\tau v_{\tau(0)} \cdots v_{\tau(k)}$ for any $\tau \in S_{k+1}$.

Note 14. $C_k(K, \Sigma)$ is a free abelian group.

Definition. Define the *differential* $\partial_k : C_k(K, \Sigma) \to C_{k-1}(K, \Sigma)$ by

$$\partial_k(v_0 \cdots v_k) = \sum_{i=0}^{k} (-1)^i v_0 \cdots \widehat{v_i} \cdots v_k,$$

which we extend linearly.

Exercise 3. Show that $\partial^2 = 0$.

Example 20. $v_0 v_1 v_2 \overset{\partial_2}{\mapsto} v_1 v_2 - v_0 v_2 + v_0 v_1 \overset{\partial_1}{\mapsto} v_2 - v_1 - (v_2 - v_0) + v_1 - v_0 = 0$.

Definition. Define the *k-th homology group of* (K, Σ) as

$$H_k(K, \Sigma) = \ker \partial_k \big/ \operatorname{im} \partial_{k+1}.$$

We call $Z_k(K, \Sigma) := \ker \partial_k$ *cycles* and $B_k(K, \Sigma) := \operatorname{im} \partial_{k+1}$ *boundaries*.

3.1 Lecture 9

Note 15. The category of simplicial complexes Δ has as morphisms functions $f : (K, \Sigma_K) \to (L, \Sigma_L)$ such that $f(\sigma) \in \Sigma_L$ when $\sigma \in \Sigma_K$. We call these *simplicial maps*.

Definition. A *subcomplex of K* is a set $L \subset K$ such that inclusion is a simplicial map.

Example 21. If K is a simplicial complex, then $K^p := \{\sigma \in \Sigma_K : |\sigma| \leq p + 1\}$.

Definition. If K is a simplicial complex, then define $|K|$ as the set

$$\{\alpha : K \to I \mid \sum_{v \in K} \alpha(v) = 1 \wedge \{v \mid \alpha(v) \neq 0\} \in \Sigma_K\}.$$

Let $|K|_d$ denote this set endowed with the topology induced by the metric given by

$$d(\alpha, \beta) = \sqrt{\sum_{v \in K} |\alpha(v) - \beta(v)|^2}.$$

Example 22. Let $K = \{0, 1, \ldots, n\}$ and let Σ consist of all finite subsets of K. Then

$$|K|_d = \{(\alpha(0), \ldots, \alpha(n)) \mid \alpha(0) + \cdots + \alpha(n) = 1\} \cong_{\textbf{Set}} \Delta^n,$$

which recovers the Euclidean metric.

Note 16.

1. When $\sigma \in \Sigma_K$ is a q-simplex, there exists a natural map $|\sigma^q|_d : \Delta^q \to |K|_d$ given by mapping x to the function α where $\alpha(\sigma) = x$ and $\alpha(v) = 0$ for any $v \notin \sigma$.

2. Define a new topology on $|K|$ where $A \subset |K|$ is closed (resp. open) if $(|\sigma|_d)^{-1}(A)$ is closed (resp. open) in $\Delta^{|\sigma|-1}$ for each $\sigma \in \Sigma_K$. From now on, $|K|$ is assumed to have this topology.

3. Given a simplicial map $f : K \to L$, define the map $|f| : |K| \to |L|$ by $\alpha \mapsto (w \mapsto \sum_{v \in f^{-1}(w)} \alpha(v))$. Thus, we get a functor $|\cdot| : \Delta \to \textbf{Top}$.

Definition. A *triangulation of a space* X is a pair $((K, \Sigma), \varphi)$ such that $\varphi : |K| \to X$ is a homeomorphism.

Remark 13. The Cantor set has no triangulation.

Definition. The category of *chain complexes* **Ch** has as objects sequences of abelian groups of the form

$$A_0 \xleftarrow{\partial_1} A_1 \xleftarrow{\partial_2} A_2 \xleftarrow{\partial_3} A_3 \xleftarrow{\partial_3} \cdots$$

such that $\partial_i \partial_{i+1} = 0$ for each $i \in \mathbb{N}$. Its morphisms are commutative diagrams of the form

$$
\begin{array}{ccccccccc}
A_0 & \xleftarrow{\partial_1} & A_1 & \xleftarrow{\partial_2} & A_2 & \xleftarrow{\partial_3} & A_3 & \xleftarrow{\partial_4} & \cdots \\
\downarrow{\scriptstyle f_0} & & \downarrow{\scriptstyle f_1} & & \downarrow{\scriptstyle f_2} & & \downarrow{\scriptstyle f_3} & & \\
B_0 & \xleftarrow[\partial_1']{} & B_1 & \xleftarrow[\partial_2']{} & B_2 & \xleftarrow[\partial_3']{} & B_3 & \xleftarrow[\partial_4']{} & \cdots
\end{array}
,
$$

so that $\partial_{i-1} f_i = f_{i-1} \partial_{i-1}$ for each i. In this case, we call $f := (f_i)_{i \in \mathbb{Z}}$ a *chain map*.

Definition.

1. Given a chain complex (A, ∂), define its *i-th homology group* as

$$H_i(A, \partial) = {}^{Z(A_i)}\!/_{B(A_i)}$$

where $\underbrace{Z_i := \ker \partial_i}_{cycles}$ and $\underbrace{B_i := \operatorname{im} \partial_{i+1}}_{boundaries}$.

2. Any morphism $f : (A, \partial) \to (B, \partial')$ induces a map $H_q(f) : H_q(A) \to H_q(B)$. We say that f is a *quasi-isomorphism* if $H_q(f)$ is an isomorphism for each q.

Note 17. Any chain map preserves both cycles and boundaries.

Note 18. We get a functor $C_\bullet : \Delta \to \textbf{Ch}$ given by $(K, \Sigma) \mapsto (C_q(K, \Sigma), \partial_q)_{q \geq 0}$. As a result, we find ourselves with the following diagram of functors.

$$
\begin{array}{ccc}
\Delta & \xrightarrow{\;|\cdot|\;} & \textbf{Top} \\
{\scriptstyle C_\bullet}\downarrow & & \\
\textbf{Ch} & \xrightarrow{\;H_\bullet\;} & \textbf{Ab}
\end{array}
$$

Remark 14. (Singular simplex) The *Hauptvermutung* is the conjecture that if X is a nice topological space such as a manifold, then for any two triangulations of X, you can get from one to the other in a combinatorial way. It turns out that this is false. Hence we cannot fill our above diagram with a functor **Top** $\to \Delta$.

Eilenberg and Steenrod, however, created the following approach to obtain certain reverse arrows in our diagram. Let X be a space. A *singular q-simplex on X* is a continuous map $\Delta^q \to X$. Let $\mathrm{Sing}_q(X)$ denote the set of all singular q-simplices on X. Let $C_q(X)$ be the free abelian group on $\mathrm{Sing}_q(X)$. Define $\partial_q : C_q(X) \to C_{q-1}(X)$ by

$$\sigma \mapsto \sum_{i=0}^{q} (-1)^i \sigma \restriction_{[v_0,\ldots,\widehat{v_i},\ldots,v_q]}$$

where $\Delta^q \cong [v_0,\ldots,v_q]$. Then $\partial_{q-1}\partial_q = 0$. We now have a functor **Top** $\to$ **Ch** that maps each map $f : X \to Y$ of spaces to the chain map (f_n) where $f_n(g : \Delta^n \to X) = f \circ g_n$. Note that the induced homology functor **Top** $\to$ **Ab** is a topological invariant.

Note 19. Suppose that $F : X \times I \to Y$ is a homotopy from f to g. Then we want to show that $H_q(f) = H_q(g)$ for each q. Although $\Delta^q \times I$ is not a simplex, we can write $\Delta^q \times \{0\} = [v_0,\ldots,v_q]$ and $\Delta^q \times \{1\} = [v_0',\ldots,v_q']$ and consider the following decomposition of $\Delta^q \times I$ into simplices.

$$[v_0, v_1, \ldots, v_q]$$
$$[v_0, \ldots, v_q, v_q']$$
$$[v_0, \ldots, v_{q-1}, v_{q-1}', v_q']$$
$$\vdots$$
$$[v_0', v_1', \ldots, v_q']$$

Definition. Let (A, ∂) and (B, ∂) be two chain complexes and $f, g : (A, \partial_A) \to (B, \partial_B)$ two chain maps. A *chain homotopy between f and g* is a map $H : A_q \to B_{q+1}$ for each q such that $\partial_B H + H \partial_A = f - g$.

Proposition 12. If f and g are chain homotopic, then $H_q(f) = H_q(g)$.

Note 20. Let H be a chain homotopy between f and g. If $x \in A_q$ and $\partial x = 0$, then $f(x) - g(x) = (\partial H + H\partial)(x) = \partial H(x)$, so that $f(x) - g(x)$ is a boundary.

3.2 Lecture 10

Lemma 18. Let $F : X \times I \to Y$ be a homotopy between f and g. Decompose $\Delta^k \times I$ into $k+1$ simplices. Label the vertices of $\Delta^k \times \{0\}$ and $\Delta^k \times \{1\}$ by $v_0,\ldots,v_k$ and $w_0,\ldots,w_k$, respectively. Then $\bigcup_{i=0}^{k} \underbrace{[v_0, v_1, \ldots, v_i, w_i, \ldots, w_k]}_{\text{convex span}}$. For each k, define the map $p : C_k(X) \to C_{k+1}(Y)$ by

$$p\sigma = \sum_{i} (-1)^i F \circ (\sigma \times \mathbb{1}_I \restriction_{[v_0,\ldots,v_i,w_i,\ldots,w_k]}).$$

Then p is a chain homotopy between f_* and g_*.

Proof. We just verify some low-dimensional cases. First, consider a simplex $\sigma : \Delta^1 \to X$. Then

$$\partial p\sigma = (F \circ \sigma \times \mathbb{1})[v_0, w_0] + (F \circ \sigma \times \mathbb{1})[w_0, w_1] - (F \circ \sigma \times \mathbb{1})[v_1, w_1] - (F \circ \sigma \times \mathbb{1})[v_0, v_1].$$
$$p\partial\sigma = -(F \circ \sigma \times \mathbb{1})[v_0, w_0] + (F \circ \sigma \times \mathbb{1})[v_1, w_1].$$

Thus,
$$\partial p\sigma + p\partial\sigma = (F \circ \sigma \times \mathbb{1})[w_0, w_1] - (F \circ \sigma \times \mathbb{1})[v_0, v_1] = g\sigma - f\sigma.$$

Next, consider a simplex $\sigma : \Delta^2 = [v_0, v_1, v_2] \to X$ Note that

$$p\sigma = [v_0, w_0, w_1, w_2] - [v_0, v_1, w_1, w_2] + [v_0, v_1, v_2, w_2].$$

From this we compute

$$\partial p\sigma = [w_0, w_1, w_2] - [v_0, w_1, w_2] + [v_0, w_0, w_2] - [v_0, w_0, w_1]$$
$$- [v_1, w_1, w_2] + [v_0, w_1, w_2] - [v_0, v_1, w_2] + [v_0, v_1, w_1]$$
$$+ [v_1, v_2, w_2] - [v_0, v_2, w_2] + [v_0, v_1, w_2] - [v_0, v_1, v_2].$$

Moreover,

$$\partial\sigma = \sigma\restriction_{[v_1, v_2]} - \sigma\restriction_{[v_0, v_2]} + \sigma\restriction_{[v_0, v_1]},$$

so that

$$p\partial\sigma = \sigma\restriction_{[v_1, w_1, w_2]} - \sigma\restriction_{[v_1, v_2, w_2]} - \sigma\restriction_{[v_0, w_0, w_2]} + \sigma\restriction_{[v_0, v_2, w_2]} + \sigma\restriction_{[v_0, w_0, w_1]} - \sigma\restriction_{[v_0, v_1, w_1]}.$$

We conclude that $\partial p\sigma + p\partial\sigma = (F \circ \sigma \times \mathbb{1})[w_0, w_1, w_2] - (F \circ \sigma \times \mathbb{1})[v_0, v_1, v_2] = g\sigma - f\sigma.$ □

Corollary 8. If $X \simeq Y$, then $H_*(X) \cong H_*(Y)$.

Proof. Our previous lemma shows that $H_*(-)$ is actually a functor **Htpy** $\to$ **Ab**. Hence our result follows from the fact that functors preserve the identity morphism. □

Example 23. Let $X = \{x_0\}$, so that $\mathrm{Sing}_k(X) = \{c_{x_0} : \Delta^k \to \{x_0\}\}$. Then

$$C_*(X) = \mathbb{Z} \xleftarrow{\ \partial\ } \mathbb{Z} \xleftarrow{\ \partial\ } \mathbb{Z} \xleftarrow{\ \partial\ } \mathbb{Z} \xleftarrow{\ \partial\ } \cdots.$$

Note that $\partial c_{x_0} = c_{x_0}([v_1]) - c_{x_0}([v_0]) = 0$ when $c_{x_0} : \Delta^1 \to X$. If $c_{x_0} : \Delta^k \to X$, then

$$\partial c_{x_0} = \sum_{i=0}^{k} (-1)^i \underbrace{c_{x_0}\restriction_{[v_0, \ldots, \hat{v}_i, \ldots, v_k]}}_{c_{x_0} : \Delta^{k-1} \to X}.$$

Hence $\partial_k : C_k(X) \to C_{k-1}(X)$ equals 0 if k is odd and $\mathbb{1}$ if k is even. As a result, we get a sequence in homology

$$\mathbb{Z} \qquad 0 \qquad 0 \qquad 0 \qquad \cdots$$

Corollary 9. If X is contractible, then $H_*(X) = \begin{cases} \mathbb{Z} & * = 0 \\ 0 & * \neq 0 \end{cases}.$

Lemma 19. $H_*(X) \cong \bigoplus_{X_\alpha \in \pi_0(X)} H_*(X_\alpha).$

Proof. Note that

$$\mathrm{Map}(\Delta^k, X) \cong_{\mathbf{Set}} \mathrm{Map}(\Delta^k, \coprod_\alpha X_\alpha)$$
$$\cong_{\mathbf{Set}} \coprod_\alpha \mathrm{Map}(\Delta^k, X_\alpha)$$

because Δ^k is path connected. Therefore, $C_*(X) \cong \bigoplus_\alpha C_*(X_\alpha).$ □

Note 21. Our proof of the last theorem shows that the functor $C_*(-) : \mathbf{Top} \to \mathbf{Ch}$ preserves coproducts.

Lemma 20. The functor $H_*(-) : \mathbf{Ch} \to \mathbf{Ab}$ preserves coproducts.

Proof. Let S be a set and (A_s, ∂) be a chain complex for each $s \in S$. Note that $\bigoplus_S H_n(A) = \bigoplus_S \ker \partial_n / \mathrm{im}\, \partial_{n+1}$ and $H_n(\bigoplus_S A) = \ker \bigoplus_S \partial_n / \mathrm{im} \bigoplus_S \partial_{n+1}$. But **Ch** and **Ab** have arbitrary direct sums, and the bifunctor $\bigoplus(-, -)$ commutes with kernels. Since $\bigoplus$ always commutes with images and with quotients, it follows that $\bigoplus_S H_n(A) = H_n(\bigoplus_S A)$, as desired. □

Example 24. $H_*(S^0) = \begin{cases} \mathbb{Z} \times \mathbb{Z} & * = 0 \\ 0 & * \neq 0 \end{cases}$.

Definition. (Reduced homology) Define $\epsilon : C_0(X) \to \mathbb{Z}$ by $\sum a_x \cdot x \mapsto \sum a_x$. Note that

$$(\epsilon \circ \partial)(\sigma : \Delta^1 \to X) = \epsilon(1 \cdot \sigma(v_1) - 1 \cdot \sigma(v_0)) = 1 - 1 = 0.$$

This induces a map $\epsilon : H_0(X) \to \mathbb{Z}$. Let

$$\widetilde{C}_k(X) = \begin{cases} C_k(X) & k > 0 \\ \ker \epsilon & k = 0 \end{cases}.$$

Define

$$\widetilde{H}_k(X) = H_k(\widetilde{C}_k(X)).$$

Note that $\widetilde{H}_k(X) = H_k(X)$ for any $k > 0$.

Note 22.

1. $\widetilde{H}_*(\{x_0\}) = 0$.

2. Both $\widetilde{C}(-)$ and $\widetilde{H}(-)$ are functors and homotopy invariant.

Example 25. $\widetilde{H}_k(S^n) \cong \begin{cases} \mathbb{Z} & k = n \\ 0 & k \neq n \end{cases}$.

Proposition 13. $H_0(X) \cong \widetilde{H}_0(X) \oplus \mathbb{Z}$

Proof. We have a commutative diagram

The three columns and the top two rows are exact. The nine lemma implies that the bottom row is exact. □

Corollary 10. $\widetilde{H}_0(X) = 0$ whenever X is path connected.

Definition. (Relative homology) Given a pair (X, A) with $A \subset X$, define $C_*(X, A) = C_*(X)/C_*(A)$. Since $\partial : C_*(A) \to C_*(A)$, this descends to a map $\partial : C_*(X, A) \to C_*(X, A)$. Define $H_*(X, A) = H_*(C_*(X, A))$.

Example 26.

1. Consider the pair $(\mathbb{R}, [0, 3])$. Let $\sigma : \Delta^1 \to [0, 3] \subset \mathbb{R}$. Then $\partial \sigma = [3] - [0]$, so that $[0] = [3]$ in $C_0(\mathbb{R}, [0, 3])$.

2. Consider the pair $(\mathbb{R}, \mathbb{R} \setminus (0, 1))$. Choose $[x_0] \in C_0(A)$ and $[x_1] \in C_0((0, 1))$. Let $\sigma : \Delta^1 \xrightarrow{\cong} [x_1, 1]$. Then $\partial \sigma = [1] - [x_1]$. As $[1] \in C_0(A)$, we see that $[x_1] = \partial \sigma$ in $C_0(\mathbb{R}, \mathbb{R} \setminus (0, 1))$.

Definition. We say that a pair (X, A) is *good* if there is some neighborhood $U \subset X$ of A such that U deformation retracts onto A.

Theorem 10. If (X, A) is a good pair, then $H_*(X, A) \cong \widetilde{H}_*(X/A)$.

Example 27. $H_*(D^n, S^{n-1}) \cong \widetilde{H}_*(S^n)$.

Lemma 21. Let X be a path connected space and $A \subset X$.

1. $H_0(X) \cong \mathbb{Z}$.

2. The map $i_* : H_0(A) \to H_0(X)$ induced by inclusion is surjective.

Proof.

1. Consider $x \in X$ as a vertex. For any vertex $y \in X$, there is some path $c : x \rightsquigarrow y$. Note that $c \in C_1(X)$ and that $\partial c = y - x$. Hence $[y] = [x]$ in $H_0(X)$. This shows that $H_0(X) \cong \langle [x] \rangle \cong \mathbb{Z}$.

2. Let $[x]$ generate $H_0(X)$ and let $y \in Y$. We can find a path $i(y) \rightsquigarrow x$. Hence $x - i(y) \in B_0(X)$, so that $[x] = [i(y)] = i_*([y])$. This shows that i_* is surjective.

$\square$

Lemma 22. (Snake) Suppose that A, B, and C are three chain complexes and $i : A \to B$ and $j : B \to C$ are chains maps such that for each k, the sequence $0 \to A_k \to B_k \to C_k \to 0$ is exact. Then there exists a *long exact sequence in homology*

$$
\cdots \longrightarrow H_k(A) \longrightarrow H_k(B) \longrightarrow H_k(C)
$$
$$
\xrightarrow{\partial'}
$$
$$
H_{k-1}(A) \longleftarrow H_{k-1}(B) \longrightarrow H_{k-1}(C) \longrightarrow \cdots
$$

Proof. We have a commutative diagram with exact rows

$$
\begin{array}{ccccccccc}
0 & \longrightarrow & A_{k+1} & \xrightarrow{i} & B_{k+1} & \xrightarrow{j} & C_{k+1} & \longrightarrow & 0 \\
& & \downarrow{\partial} & & \downarrow{\partial} & & \downarrow{\partial} & & \\
0 & \longrightarrow & A_k & \xrightarrow{i} & B_k & \xrightarrow{j} & C_k & \longrightarrow & 0 \\
& & \downarrow{\partial} & & \downarrow{\partial} & & \downarrow{\partial} & & \\
0 & \longrightarrow & A_{k-1} & \xrightarrow{i} & B_{k-1} & \xrightarrow{j} & C_{k-1} & \longrightarrow & 0 \\
& & \downarrow{\partial} & & \downarrow{\partial} & & \downarrow{\partial} & & \\
0 & \longrightarrow & A_{k-2} & \xrightarrow{i} & B_{k-2} & \xrightarrow{j} & C_{k-2} & \longrightarrow & 0
\end{array}
$$

Let $c \in C_k$ such that $\partial c = 0$. By exactness, there exists $b \in B_k$ such that $j(b) = c$. Then $\partial b \in B_{k-1}$ such that $j\partial b = \partial j b = \partial c = 0$. Hence there exists a unique $a \in A_{k-1}$ such that $i(a) = \partial b$. Then $i\partial a = \partial i a = \partial\partial b = 0$. Since i is injective, this implies that $\partial a = 0$. Define the map $\partial' : H_k(C) \to H_{k-1}(A)$ by $[c] \mapsto [a]$.

Exercise 4.

1. Show that $\partial : H_k(C) \to H_{k-1}(A)$ by $c \mapsto a$ is a well-defined homomorphism.

   Proof. Suppose that $j(b') = c$. Then $b - b' \in \ker j = \operatorname{im} i$, so that $i(u) = b - b'$ for some $u \in A_k$. Then

$$
\begin{aligned}
i(a) - \partial b' & \\
&= \partial b - \partial b' \\
&= \partial b - b' \\
&= \partial i u \\
&= i \partial u.
\end{aligned}
$$

Therefore, $\partial b' = i(a - \partial u)$. Since $[a] = [a - \partial u]$ in $H_{k-1}(A)$, we see that a is independent of our choice of b. From now on, we will denote such an a by a_c. It is clear that ∂' is also independent of our choice of $c \in \ker \partial$ and thus is well-defined. Finally, it is straightforward to check that it is a homomorphism. $\square$

2. Verify that the given long sequence is exact both at $H_k(C)$ and at $H_{k-1}(A)$.

   Proof.
   $\underline{H_k(C)}$: We must show that $\operatorname{im} j(\bullet) = \ker \partial'$.

   Let $[f] \in \operatorname{im} j(\bullet)$, so that $[f] = [j(g)]$ for some $g \in Z(B_k) = \ker \partial$. Note that $i(a_c) = \partial g = 0$. As i is injective, it follows that $\partial([f]) = [a_c] = 0$, i.e., $\operatorname{im} j(\bullet) \subset \ker \partial'$.

   Conversely, suppose that $[f] \in \ker \partial'$. Then $a_c \in \operatorname{im} \partial$, so that $a_c = \partial(\tilde{f})$ for some $\tilde{f}$. Moreover, $f = j(g)$ for some g. Letting $y := i(\tilde{f})$, we get

   $$\partial(y) = \partial(i(\tilde{f})) = i(\partial(\tilde{f})) = i(a_c)$$

   and

   $$j(g - y) = j(g) - j(y) = f - \underbrace{j(i(\tilde{f}))}_{ji=0} = f.$$

   Therefore, $\partial(g - y) = i(a_c) - i(a_c) = 0$, so that $g - y \in \ker \partial = Z(B_k)$. Since $[j(g - y)] = [f]$, it follows that $[f] \in \operatorname{im} j(\bullet)$, i.e., $\operatorname{im} j(\bullet) \supset \ker \partial'$.

   $\underline{H_{k-1}(A)}$: We must show that $\ker i(\bullet) = \operatorname{im} \partial'$. The fact that $\ker i(\bullet) \supset \operatorname{im} \partial'$ is evident from our construction of ∂'.

   Conversely, let $[f] \in \ker i(\bullet)$, so that $[if] = 0$. Then $if = \partial g$ for some $g \in B_k$. Hence $f = a_c$ for some $c \in j^{-1}(g)$. This implies that $\partial'([c]) = [a_c] = [f]$, so that $[f] \in \operatorname{im} \partial'$. $\square$

$\square$

Corollary 11. Note that we have a canonical short exact sequence $0 \to C_*(A) \to C_*(X) \to C_*(X, A) \to 0$. Therefore, for any pair (X, A), there exists a long exact sequence

$$
\begin{array}{ccccccc}
\cdots \longrightarrow & H_{k+1}(X, A) & \longrightarrow & H_k(A) & \longrightarrow & H_k(X) & \longrightarrow & H_k(X, A) \\
\\
& H_{k-1}(A) & \longleftarrow & H_{k-1}(X) & \longrightarrow & H_{k-1}(X, A) & \longrightarrow & \cdots \\
\\
& H_0(A) & \longleftarrow & H_0(X) & \longrightarrow & H_0(X, A) & \longrightarrow & 0
\end{array}
$$

Note 23. By Lemma 21, the bottom row

$$H_0(A) \longrightarrow H_0(X) \longrightarrow H_0(X, A) \longrightarrow 0$$

is precisely $\mathbb{Z} \to \mathbb{Z} \to 0 \to 0$ when X and A are path connected.

Definition. A *triangle of spaces* is a triple (X, A, B) such that $X \supset A \supset B$.

Corollary 12. Let (X, A, B) be a triangle. The short exact sequence $0 \to C_*(A, B) \to C_*(X, B) \to C_*(X, A) \to 0$ induces a long exact sequence

$$\cdots \to H_k(A, B) \to H_k(X, B) \to H_k(X, A) \to H_{k-1}(A, B) \to \cdots.$$

3.3 Lecture 11

Theorem 11. (Excision) If (X, A) is a pair and $Z \subset A$ such that $\mathrm{cl}(Z) \subset \mathring{A}$. Then you can *excise* Z in that the inclusion of pairs $(X \setminus Z, A \setminus Z) \hookrightarrow (X, A)$ induces an isomorphism of homology.

Corollary 13. If (X, A) is a good pair, then the natural projection $q : (X, A) \to (X/A, A/A)$ induces an isomorphism on homology

$$H_*(X, A) \to H_*(X/A, A/A) \cong \widetilde{H}_*(X/A).$$

Proof. There is some neighborhood U of A that deformation retracts onto A. For each k, the diagram

$$
\begin{array}{ccccc}
H_k(X, A) & \xrightarrow{\ \ 1\ \ } & H_k(X, U) & \xleftarrow{\ \ 2\ \ } & H_k(X \setminus A, U \setminus A) \\
\Big\downarrow{\scriptstyle 5} & & \Big\downarrow{\scriptstyle 6} & & \Big\downarrow{\scriptstyle 7} \\
H_k(X/A, A/A) & \xrightarrow[\ \ 3\ \ ]{} & H_k(X/A.U/A) & \xleftarrow[\ \ 4\ \ ]{} & H_k(X/A \setminus A/A, U/A \setminus A/A)
\end{array}
$$

commutes. Arrow 1 is an isomorphism due to the exactness of the sequence

$$\underbrace{H_k(U, A)}_{0} \to H_k(X, A) \to H_k(X, U) \to \underbrace{H_{k-1}(U, A)}_{0}$$

obtained from Corollary 11. Similarly, arrow 3 is an isomorphism. Arrows 2 and 4 are isomorphisms by excision. Arrow 7 is an isomorphism since $(X \setminus A, U \setminus A) \hookrightarrow (X/A \setminus A/A, U/A \setminus A/A)$ is a homeomorphism of pairs. Therefore, arrow 5 is an isomorphism since out diagram commutes. . $\qquad\square$

Definition. A based space (X, x_0) is *nondegenerate* if the pair $(X, \{x_0\})$ is good.

Corollary 14. Let $\{(X_\alpha, x_\alpha)\}_\alpha$ be a set of nondegenerate bases spaces. Then $\widetilde{H}_*(\bigvee_\alpha X_\alpha) \cong \bigoplus_\alpha \widetilde{H}_*(X_\alpha)$.

Proof. Note that $\bigvee_\alpha X_\alpha = \coprod_\alpha X_\alpha / \coprod_\alpha \{x_\alpha\}$. Now apply Corollary 12 together with the fact that the functor $H_*(-, -) : \mathbf{Top} \times \mathbf{Top} \to \mathbf{Ab}$ preserves coproducts. $\qquad\square$

Definition. Let (K, Σ) be a simplicial complex and $L \subset K$ a subcomplex. Then $C_*(K) / C_*(L) = C_*(K, L)$. Recall that

$$|K| = \{f : K \to I \mid \{v \in K \mid f(v) \neq 0\} \in \Sigma, \ \sum_{v \in K} f(v) = 1\}.$$

Define $\varphi : C_k(K) \to C_k(|K|)$ by $[v_0, v_1, \ldots, v_k] \mapsto (\sigma_{[v_0, \ldots, v_k]} : \Delta^k \to |K|)$ where

$$\sigma_{[v_0, \ldots, v_k]}(t_0, \ldots, t_k)(v \in K) = \begin{cases} t_i & v = v_i \\ 0 & v \neq v_i \end{cases},$$

extended by linearity. This induces a map $\varphi : C_*(K) \to C_*(|K|)$.

Exercise 5. Check that $\varphi \partial = \partial \varphi$.

Definition. For each I, define the *i-skeleton K^i of K* to be the simplicial complex (K, Σ_{K^i}) where

$$\Sigma_{K^i}^j = \begin{cases} \Sigma_K^j & j \leq i \\ \emptyset & j > i \end{cases}.$$

Note 24. We have that $C_i(K^0) = \begin{cases} \mathbb{Z}[\Sigma_K^0] & i = 0 \\ 0 & i > 0 \end{cases}$. Since $\boxed{|K^0| = K^0}$, it follows that $H_*(|K^0|) = \mathbb{Z}[K^0]$.

Lemma 23. $\varphi : H_*(K) \to H_*(|K|)$ is an isomorphism.

Proof. Induct on the k-skeleton of K. The case where $k = 0$ is obvious. Suppose that $\varphi : H_*(K^i) \xrightarrow{\cong} H_*(|K^i|)$. Note that

$$C_*(K^{i+1}, K^i) = C_*(K^{i+1}) \big/ C_*(K^i) \cong \begin{cases} \mathbb{Z}[\Sigma_{K^{i+1}}^{i+1} = \Sigma_K^{i+1}] & * = i + 1 \\ 0 & * \neq i + 1 \end{cases}.$$

Therefore, $H_{i+1}(K^{i+1}, K^i) \cong \mathbb{Z}[\Sigma_K^{i+1}]$. Moreover, observe that $K^{i+1}/K^i \cong \bigvee_{\sigma \in \Sigma_K^{i+1}} S_\sigma^{i+1}$. From this we get

$$H_*(|K^{i+1}|, |K^i|) \cong \widetilde{H}_*(|K^{i+1}|/|K^i|) \cong \begin{cases} \mathbb{Z}[\Sigma_{K^{i+1}}^{i+1} = \Sigma_K^{i+1}] & * = i + 1 \\ 0 & * \neq i + 1 \end{cases}.$$

We now have a commutative diagram with exact rows

$$\begin{array}{ccccccccccccc}
H_{i+2}(K^{i+1}, K^i) & \longrightarrow & H_{i+1}(K^i) & \longrightarrow & H_{i+1}(K^{i+1}) & \longrightarrow & H_{i+1}(K^{i+1}, K^i) & \longrightarrow & H_i(K^i) & \longrightarrow & H_i(K^{i+1}) & \longrightarrow & H_i(K^{i+1}, K^i) \\
\downarrow{\scriptstyle\varphi\cong} & & \downarrow{\scriptstyle\varphi\cong} & & \downarrow{\scriptstyle\varphi} & & \downarrow{\scriptstyle\varphi\cong} & & \downarrow{\scriptstyle\varphi\cong} & & \downarrow{\scriptstyle\varphi} & & \downarrow{\scriptstyle\varphi\cong} \\
H_{i+2}(|K^{i+1}|, |K^i|) & \longrightarrow & H_{i+1}(|K^i|) & \longrightarrow & H_{i+1}(|K^{i+1}|) & \longrightarrow & H_{i+1}(|K^{i+1}|, |K^i|) & \longrightarrow & H_i(|K^i|) & \longrightarrow & H_i(|K^{i+1}|) & \longrightarrow & H_i(|K^{i+1}|, |K^i|)
\end{array}.$$

Lemma 24. (Five lemma) Consider the following commutative diagram in an abelian category with exact rows.

$$\begin{array}{ccccccccc}
A_1 & \longrightarrow & A_2 & \longrightarrow & A_3 & \longrightarrow & A_4 & \longrightarrow & A_5 \\
\downarrow{\scriptstyle f_1} & & \downarrow{\scriptstyle f_2} & & \downarrow{\scriptstyle f_3} & & \downarrow{\scriptstyle f_4} & & \downarrow{\scriptstyle f_5} \\
B_1 & \longrightarrow & B_2 & \longrightarrow & B_3 & \longrightarrow & B_4 & \longrightarrow & B_5
\end{array}$$

If f_2 and f_4 are isos, f_1 is epi, and f_5 is mono, then f_3 is iso.

As a result, $\varphi : H_*(K^{i+1}) \cong H_*(|K^{i+1}|)$. By induction, we are done. $\qquad\square$

Note 25. If $i \geq j + 1$, then $C_j(K) = C_j(K^i)$, so that $H_j(K) \cong H_j(K^i)$.

Proposition 14. A map $\psi : C \to |K|$ with C a compact space has $\operatorname{im}\psi \subset |K^i|$ for some i.

Corollary 15. $H_*(|K|) = \underbrace{\varinjlim H_*(|K^i|)}_{\text{direct limit}}$.

Proof. Any cycle $c \in C_i(|K|)$ is finite linear combination of singular simplices. Our previous proposition implies that there exists $j \geq 0$ small enough so that $c \in C_i(K^j|)$ and $[c] \neq 0 \in H_i(|K^j|)$. $\qquad\square$

3.4 Lecture 12

Theorem 12. (Excision) If (X, A) is a pair and $Z \subset A$ such that $\operatorname{cl}(Z) \subset \mathring{A}$. Then you can *excise Z* in that the inclusion of pairs $(X \setminus Z, A \setminus Z) \hookrightarrow (X, A)$ induces an isomorphism of homology.

Lemma 25. The excision theorem holds if and only if whenever $X = \mathring{A} \cup \mathring{B}$, the inclusion of pairs $(B, A \cap B) \to (X, A)$ induces an isomorphism on homology $H_*(B, A \cap B) \to H_*(X, A)$.

Proof. For the forward direction, set $Z = X \setminus B$. Conversely, set $B = X \setminus Z$. $\qquad\square$

Definition. Let X be a space. Let $\mathcal{U} = \{\mathring{U}_\alpha\}$ be a cover of X with each $U_\alpha \subset X$.

1. Define $\operatorname{Sing}_n^{\mathcal{U}}(X) = \{\sigma : \Delta^n \to X \mid \operatorname{im}\sigma \subset U_\alpha \text{ for some } \alpha\}$. We call elements of this set *small simplices relative to $\mathcal{U}$*.

2. Define $C_n^{\mathcal{U}}(X) = \mathbb{Z}[\operatorname{Sing}_n^{\mathcal{U}}(X)]$.

Theorem 13. The inclusion map $i : C_*^{\mathcal{U}}(X) \to C_*(X)$ is a *chain homotopy equivalence*, i.e., there exists $\rho : C_*(X) \to C_*^{\mathcal{U}}(X)$ such that both ρi and $i\rho$ are chain homotopic to $\mathbb{1}$.

28

Definition.

1. Given an n-simplex $\sigma = [v_0, v_1, \ldots, v_n]$, the *barycenter of σ* is the point $b := \sum_{i=0}^{n} t_i v_i$ where $t_i = \frac{1}{n+1}$ for each $i = 0, \ldots, n$.

2. Define the *barycentric subdivision B_σ of σ* recursively as follows.

   - If $\sigma = [v_0]$, then let $B_\sigma = \sigma$.
   - If $\sigma = [v_0, v_1, \ldots, v_n]$, then let B_σ consist of the n-simplices $[b, w_0, \ldots, w_{n-1}]$ where $[w_0, \ldots, w_{n-1}]$ is an $(n-1)$ simplex in the barycentric subdivision of a face of $[v_0, v_1, \ldots, v_n]$.

Figure 6: copied from Hatcher (120)

Note 26. The vertices of simplices in the barycentric subdivision of σ are precisely the barycenters of all the k-dimensional faces of σ for each $0 \le k \le n$.

Definition. The *diameter of $[v_0, \ldots, v_n]$* is $\max\limits_{0 \le i,j \le n} |v_i - v_j|$.

Lemma 26. If d denotes the diameter of $\sigma := [v_0, \ldots, v_n]$, then the diameter of any n-simplex of B_σ is at most $\frac{nd}{n+1}$.

Proof. For each i, we have that

$$|b - v_i| = \left| \frac{v_0 + \cdots + v_n}{n+1} - v_i \right|$$
$$= \left| \frac{v_0 + \cdots + v_n}{n+1} - \frac{(n+1)v_i}{n+1} \right|.$$

But $|v_i - v_i| = 0$, and $|v_k - v_i| \le d$ for each k. Hence $|b - v_i| \le \frac{nd}{n+1}$. We are done by induction on n. $\square$

Definition. Let (K, Σ_K) be a simplicial complex. Define a new simplicial complex $(K', \Sigma_{K'})$ such that $K' = \Sigma_K$ and $\Sigma_{K'}^n = \{\sigma_0 \subset \sigma_1 \subset \cdots \subset \cdots \subset \sigma_n\}$ wheere each $\sigma_i \in \Sigma_K$.

Definition. Let $\sigma : \Delta^n \to X$, which induces a map $\sigma_* : C_*(\Delta^n) \to C_*(X)$. Let $Y \subset \mathbb{R}^n$ be convex (so that we can apply barycentric subdivision to it.) For each $k \ge 0$, define the group of *linear chains $LC_k(Y)$* as the free abelian group on the set of linear maps $\Delta^k \to Y$. For convenience, let $LC_{-1}(Y) := \mathbb{Z}[\emptyset] \cong \mathbb{Z}$.

Note 27. Any linear chain $\lambda : \Delta^k \to Y$ is determined by the values $w_i := \lambda(v_i)$ where v_i denotes the i-th vertex of Δ^k. For each $b \in Y$, we have a group homomorphism $b : LC_k(Y) \to LC_{k+1}(Y)$ given by $[w_0, \ldots, w_k] \mapsto [b, w_0, \ldots, w_k]$. Note that

$$\partial b[w_0, \ldots, w_k] = \partial[b, w_0, \ldots, w_k]$$
$$= [w_0, \ldots, w_k] - \sum_{i=0}^{k} (-1)^i [b, w_0, \ldots, \hat{w}_j, \ldots, w_k]$$
$$= [w_0, \ldots, w_k] - b\partial[w_0, \ldots, w_k].$$

This shows that $\partial b + b\partial = \mathbb{1}$, so that b is a chain homotopy between $\mathbb{1}$ and and 0.

Definition. Let b_λ denote the image under λ of the barycenter of Δ^n. Define the *subdivision map* $S : LC_*(Y) \to LC_*(Y)$ recursively by

- $S(\emptyset) = \emptyset$

- $S\lambda = b_\lambda S(\partial \lambda)$.

Note 28. If λ is an embedding with $\mathrm{im}\, \lambda = [w_0, \dots, w_n]$, then $S\lambda = $ (sum of the n-simplices (up to sign) in the barycentric subdivision of $[w_0, \dots, w_n]$).

Lemma 27. $S\partial = \partial S$.

Proof. We see that $S \restriction_{LC_{-1}(Y)} = \mathbb{1}$. Also, on $LC_0(Y)$ we have that $S([v]) = b_{[v]} S(\partial [v]) = b_{[v]}(\emptyset) = [v]$. Thus, $S \restriction_{LC_0(Y)} = \mathbb{1}$ as well. Hence the equation $S\partial = \partial S$ holds on $LC_0(Y)$. If $* > 0$, then apply the fact that $\partial b_\lambda + b_\lambda \partial = \mathbb{1}$ to get

$$\begin{aligned}
\partial S\lambda &= \partial b_\lambda S)\partial \lambda \\
&= (1 - b_\lambda \partial) S(\partial \lambda) \\
&= S(\partial \lambda) - b_\lambda \partial S(\partial \lambda) \\
&= S(\partial \lambda) - \underbrace{b_\lambda S(\partial \partial \lambda)}_{\text{by induction}} \\
&= S(\partial \lambda).
\end{aligned}$$

$\square$

Remark 15. Define $T : LC_n(Y) \to LC_{n+1}(Y)$ a chain homotopy between $\mathbb{1}$ and S recursively by

- $T(\emptyset) = 0$

- $T\lambda = b_\lambda(\lambda - T\partial \lambda)$.

Then the diagram

$$\begin{array}{ccccccccccc}
\cdots & \xrightarrow{\partial} & LC_2(Y) & \xrightarrow{\partial} & LC_1(Y) & \xrightarrow{\partial} & LC_0(Y) & \xrightarrow{\partial} & LC_{-1}(Y) & \xrightarrow{\partial} & 0 \\
& & \downarrow{\scriptstyle S} & \swarrow{\scriptstyle T} & \downarrow{\scriptstyle S} & \swarrow{\scriptstyle T} & \downarrow{\scriptstyle \mathbb{1}} & \swarrow{\scriptstyle T} & \downarrow{\scriptstyle \mathbb{1}} & & \\
\cdots & \xrightarrow{\partial} & LC_2(Y) & \xrightarrow{\partial} & LC_1(Y) & \xrightarrow{\partial} & LC_0(Y) & \xrightarrow{\partial} & LC_{-1}(Y) & \xrightarrow{\partial} & 0
\end{array}$$

commutes.

Claim 2. $\partial T + T\partial = \mathbb{1} - S$.

Proof. When $n = -1$, this is immediate as $T = 0$ and $S = \mathbb{1}$. If $n > 0$, we compute

$$\begin{aligned}
\partial T\lambda &= \partial b_\lambda(\lambda - T\partial \lambda) \\
&= (\mathbb{1} - b_\lambda \partial)(\lambda - T\partial \lambda) \\
&= \lambda - T\partial \lambda - b_\lambda(\partial \lambda - \partial T\partial \lambda) \\
&= \lambda - T\partial \lambda - b_\lambda(\partial \lambda - \underbrace{(\mathbb{1} - S - T\partial)}_{\text{by induction}} \partial \lambda) \\
&= \lambda - T\partial \lambda - b_\lambda(\partial \lambda - \partial \lambda + S\partial \lambda + T\partial \partial \lambda) \\
&= \lambda - T\partial \lambda - b_\lambda S\partial \lambda \\
&= \lambda - T\partial \lambda - S\lambda.
\end{aligned}$$

$\square$

Remark 16. We extend S and T to maps $C_n(X) \to C_n(X)$ and $C_n(X) \to C_{n+1}(X)$, respectively. Let $\sigma \in C_n(X)$.

(a) Define $S\sigma = \sigma_* S \mathbb{1}_{\Delta^n}$.

(b) Define $T\sigma = \sigma_* T \mathbb{1}_{\Delta^n}$.

Some easy calculations show that S^m is a chain map for any $m \geq 0$ and that T is a chain homotopy between $\mathbb{1}$ and S.

(c) For each $m \geq 1$, define the map $T_m = \sum_{j=0}^{m-1} TS^j$.

Then T_m is a homotopy between $\mathbb{1}$ and S^m. Indeed,

$$
\begin{aligned}
\partial T_m + T_m \partial &= \partial \sum_{j=0}^{m-1} TS^j + \sum_{j=0}^{m-1} TS^j \partial \\
&= \sum_{j=0}^{m-1} \partial TS^j + TS^j \partial \\
&= \sum_{j=0}^{m-1} \partial TS^j + T\partial S^j \\
&= \sum_{j=0}^{m-1} (\mathbb{1} - S)S^j = \mathbb{1} - S^m.
\end{aligned}
$$

Lemma 28. (Lebesgue covering) Let Z be a compact metric space. Let $\mathcal{U} = \{U_\alpha\}$ be an open cover of Z. Then $\exists \delta > 0$ (called a *Lebesgue number for* $\mathcal{U}$) such that for any set S with $\mathrm{diam}(S) < \delta$, S is contained in U_α for some α.

Note 29. Let X be any space. Let $\mathcal{U} = \{\mathring{U}_\alpha\}$ be a cover of X. If $\sigma : \Delta^n \to X$, then consider the open cover $\{\sigma^{-1}(U_\alpha)\}$ of Δ^n. Any n-simplex in the m-th iteration of the barycentric subdivision of Δ^n has diameter $d' \leq (\frac{n}{n+1})^m d$ where d denotes the diameter of Δ^n. Then d' is less than a Lebesgue number for $\{\sigma^{-1}(U_\alpha)\}$ when m is large enough, in which case $S^m(\sigma) \in C_n^{\mathcal{U}}(X)$.

   Define $m(\sigma)$ as the smallest $m \in \mathbb{N}$ such that $S^m(\sigma) = C_n^{\mathcal{U}}(X)$. Define the map $D : C_n(X) \to C_{n+1}(X)$ by $D\sigma = T_{m(\sigma)}\sigma$.

3.5   Lecture 13

Lemma 29. Define the function $\rho : C_*(X) \to C_*(X)$ by $\rho = \mathbb{1} - \partial D - D\partial$.

1. ρ is a chain map.

2. $\mathrm{im}\,\rho \subset C_*^{\mathcal{U}}(X)$.

3. ρ is a chain homotopy inverse to the inclusion map $\iota : C_*^{\mathcal{U}}(X) \to C_*(X)$.

Proof.

1. We compute

$$
\begin{aligned}
\partial\rho\sigma &= \partial(\sigma - \partial D\sigma - D\partial\sigma) \\
&= \partial\sigma - \partial D\partial\sigma \\
&= \partial\sigma - (\mathbb{1} - D\partial - \rho)\partial\sigma \\
&= \rho\partial\sigma.
\end{aligned}
$$

2. We compute

$$
\begin{aligned}
\rho(\sigma) &= \sigma - \partial D\sigma - D\partial\sigma \\
&= \sigma - \partial T_{m(\sigma)}\sigma - D\partial\sigma \\
&= S^{m(\sigma)}\sigma + T_{m(\sigma)}\partial\sigma - D\partial\sigma
\end{aligned}
$$

31

since $\partial T_m + T_m \partial = \mathbb{1} - S^m$. Note that $S^{m(\sigma)}\sigma \in C_n^{\mathcal{U}}$ and that the term $T_{m(\sigma)}\partial\sigma - D\partial\sigma$ is a linear combination of terms $T_{m(\sigma)}(\partial\sigma_j) - T_{m(\sigma_j)}(\sigma_j)$ where each σ_j is the restriction of σ to a face of Δ^n. Since $m(\sigma_j) \leq m(\sigma)$ for each σ_j, it follows that $T_{m(\sigma)}\partial\sigma - D\partial\sigma$ is a linear combination of terms $TS^i(\sigma_j)$ such that $i \geq m(\sigma_j)$. Each of these terms belongs to $C_n^{\mathcal{U}}$ because T preserves small simplices relative to $\mathcal{U}$.

3. We know that $\partial D + D\partial = \mathbb{1} - \iota\rho$. Also, if σ is small relative to $\mathcal{U}$, then $m(\sigma) = 0$, so that $D\sigma = 0$. Thus, $\rho\iota = \mathbb{1}$.

$\square$

Proof. **(Excision theorem)** We prove the equivalent statement expressed in Lemma 25. Write $X = \mathring{A} \cup \mathring{B}$ with $A, B \subset X$. Let $\mathcal{U} = \{A, B\}$. Note that $C_*(A)$ is a subcomplex of $C_*^{\mathcal{U}}(X)$. The diagram

$$
\begin{array}{ccccccccc}
0 & \longrightarrow & C_*(A) & \longrightarrow & C_*^{\mathcal{U}}(X) & \longrightarrow & C_*^{\mathcal{U}}(X)/C_*(A) & \longrightarrow & 0 \\
& & \downarrow{\scriptstyle\text{q-iso}} & & \downarrow{\scriptstyle\text{q-iso}} & & \downarrow & & \\
0 & \longrightarrow & C_*(A) & \longrightarrow & C_*(X) & \longrightarrow & C_*(X)/C_*(A) & \longrightarrow & 0
\end{array}
$$

commutes. The five lemma implies that the third vertical arrow is a quasi-isomorphism as well. Finally, note that the inclusion map ${C_*(B)}/{C_*(A \cap B)} \to {C_*^{\mathcal{U}}(X)}/{C_*(A)}$ is a quasi-isomorphism since both the domain and codomain are free groups with basis the singular n-simplices in B that are outside A. $\square$

Corollary 16. (Mayer-Vietoris (MV) sequence) Let $X = \mathring{A} \cup \mathring{B}$. Then there exists a LES

$$
\cdots \longrightarrow H_k(A \cap B) \longrightarrow H_k(A) \oplus H_k(B) \longrightarrow H_k(X) \overset{\partial}{\longrightarrow} H_{k-1}(A \cap B) \longrightarrow \cdots .
$$

Proof. Consider the sequence

$$
0 \longrightarrow C_*(A \cap B) \overset{\varphi}{\longrightarrow} C_*(A) \oplus C_*(B) \overset{\psi}{\longrightarrow} C_*(X) \longrightarrow 0
$$

where $\varphi : c \mapsto (c, -c)$ and $\psi : (c_1, c_2) \mapsto c_1 + c_2$. It's easy to check that this is exact, inducing our desired LES.

We can describe the boundary map $\partial : H_k(X) \to H_{k-1}(A \cap B)$. Let $[c] \in H_k(X)$. Then $[c] = [x + y]$ where $x : \Delta^k \to A \subset X$ and $y : \Delta^k \to B \subset X$. Since $\partial(x + y) = 0$, we have that $\partial x = -\partial y$. Then $\partial[c] = [\partial x] = -[\partial y]$. $\square$

Example 28. Depict the orientable surface S_g of genus g as
so that $A \cap B$ is a cylinder L of finite height. Then $A \cap B = S^1$, $A \simeq S^1 \vee S^1$, and $B \simeq \underbrace{S^1 \vee \cdots \vee S^1}_{2g-2 \text{ copies}}$.

We have the MV sequence

$$
\begin{array}{ccccccccc}
H_2(A) \oplus H_2(B) & \longrightarrow & H_2(S_g) & \longrightarrow & H_1(A \cap B) & \longrightarrow & H_1(A) \oplus H_1(B) & \longrightarrow & H_1(S_g) \\
& & & & & & & & \\
H_0(A \cap B) & \longleftarrow & H_0(A) \oplus H_0(B) & \longrightarrow & H_0(S_g) & & & &
\end{array}
$$

.

Note that $H_1(A \cap B)$ is generated by the attaching map γ of the 2-cell, which consists of the loop positively traversing $A \cap B$ and the loop negatively traversing $A \cap B$.
Hence γ is homologous to 0. Moreover, both L and S_g are path connected. Hence our previous sequence becomes

$$0 \oplus 0 \longrightarrow H_2(S_g) \longrightarrow \mathbb{Z} \xrightarrow{\ 0\ } \mathbb{Z}^2 \oplus \mathbb{Z}^{2g-2} \longrightarrow H_1(S_g)$$

$$\mathbb{Z} \underset{n \mapsto (n,-n)}{\longleftarrow} \mathbb{Z} \oplus \mathbb{Z} \underset{(n,m) \mapsto n+m}{\longrightarrow} \mathbb{Z}$$

with arrow labeled 0.

This implies that $H_1(S_g) \cong \mathbb{Z}^{2g}$ and $H_2(S_g) \cong \mathbb{Z}$.

Example 29. Let X be space and recall that $\Sigma X = X \times I \big/ \sim$ where $(x,0) \sim (x',0)$ and $(x,1) \sim (x',1)$. Let p_0 denote the bottom point of the suspension and p_1 the top point. We can decompose this space as

$$\Sigma X = C_+ X \cup_X C_- X$$

where $C_+ X \coloneqq \Sigma X \setminus \{p_0\}$ and $C_- X \coloneqq \Sigma X \setminus \{p_1\}$. Then both $C_+ X$ and $C_- X$ are homotopy equivalent to the cone space CX and thus are contractible. Note that $C_+ X \cap C_- X \simeq X$. Consider the MV sequence

$$H_k(X) \longrightarrow H_k(C_+ X) \oplus H_k(C_- X) \longrightarrow H_k(\Sigma X)$$

$$H_{k-1}(X) \longleftarrow H_{k-1}(C_+ X) \oplus H_{k-1}(C_- X)$$

When $k - 1 > 0$, this becomes

$$H_k(X) \longrightarrow 0 \oplus 0 \longrightarrow H_k(\Sigma X) \longrightarrow H_{k-1}(X) \longrightarrow 0 \oplus 0 ,$$

in which case $H_k(\Sigma X) \cong H_{k-1}(X)$. Moreover, the exact sequence

$$H_1(C_+ X) \oplus H_1(C_- X) \longrightarrow H_1(\Sigma X)$$

$$H_0(X) \xleftarrow{\ 0\ } H_0(C_+ X) \oplus H_0(C_- X) \longrightarrow H_0(\Sigma X)$$

shows that $H_1(\Sigma X) = 0$.

Theorem 14. (Brouwer's invariance of domain) Let $U \subset \mathbb{R}^n$ be open and $V \subset \mathbb{R}^m$ be open. If $U \cong V$, then $n = m$.

Proof. Let $x \in U$ and consider $H_*(U \setminus \{x\})$. By excision, we get $H_*(U, U \setminus \{x\}) \cong H_*(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\})$. By Corollary 10, we also get a LES

$$H_k(\mathbb{R}^n \setminus \{x\}) \longrightarrow H_k(\mathbb{R}^n) \longrightarrow H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) \longrightarrow H_{k-1}(\mathbb{R}^n \setminus \{x\}) \longrightarrow H_{k-1}(\mathbb{R}^n) .$$

Let $k \geq 2$. Then $H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) \cong H_{k-1}(\mathbb{R}^n \setminus \{x\}) \cong H_{k-1}(S^{n-1})$. It follows that

$$H_k(U, U \setminus \{x\}) \cong \begin{cases} \mathbb{Z} & k = n \\ 0 & k \neq n \end{cases} .$$

If $n > m \geq 1$, then $H_n(U, U \setminus \{x\}) \cong \mathbb{Z}$ whereas $H_n(V, V \setminus \{x'\}) \cong 0$ for any $x' \in V$. In this case, $U \not\cong V$. $\square$

3.6 Lecture 14

Lemma 30. Recall that $H_n(D^n, S^{n-1}) \cong H_n(S^n) \cong \mathbb{Z}$. Note that $(D^n, S^{n-1}) \cong (\Delta^n, \partial\Delta^n)$ and that $i_n : \Delta^n \hookrightarrow \Delta^n$ is a cycle in $C_n(\Delta^n, \partial\Delta^n)$. We claim that i_n generates $H_n(\Delta^n, \partial\Delta^n)$.

Proof. We do induction on n. For the base case, it is obvious that $H_0(\Delta^0, \underbrace{\partial\Delta^0}_{\emptyset})$ is generated by i_0. Let the subspace $\wedge \subset \partial\Delta^n$ consist of all but one of the faces of $\partial\Delta^n$. Consider the triple $(\Delta^n, \partial\Delta^n, \wedge)$. This induces the LES

$$H_n(\partial\Delta^n, \wedge) \longrightarrow H_n(\Delta^n, \wedge) \longrightarrow H_n(\Delta^n, \partial\Delta^n) \longrightarrow H_{n-1}(\partial\Delta^n, \wedge) \longrightarrow H_{n-1}(\Delta^n, \wedge) .$$

Since $H_n(\Delta^n, \wedge) = 0 = H_{n-1}(\Delta^n, \wedge)$, it follows that $\alpha : H_n(\Delta^n, \partial\Delta^n) \xrightarrow{\cong} H_{n-1}(\partial\Delta^n, \wedge)$. Moreover, obtain an isomorphism $\beta : H_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}) \xrightarrow{\cong} H_{n-1}(\partial\Delta^n, \wedge)$ from the homeomorphism of pairs $(\Delta^{n-1}, \partial\Delta^{n-1}) \to (\partial\Delta^n, \wedge)$ that maps Δ^{n-1} to the face missing in $\wedge$. The inductive step now holds because $\alpha i_n = \partial i_n = \pm \beta i_{n-1}$. $\qquad\square$

Corollary 17. Consider the sphere

$$S^n = D^n \cup_{S^{n-1}} D^n = \Delta^n \cup_{\partial\Delta^n} \Delta^n$$

and the inclusion maps

$$\Delta_1^n : \Delta^n \to \text{first}(\Delta^n)$$
$$\Delta_2^n : \Delta^n \to \text{second}(\Delta^n).$$

Then $\Delta_1^n - \Delta_2^n$ is a cycle. We claim that $\Delta_1^n - \Delta_2^n$ generates $\widetilde{H}_n(S^n)$.

Proof. We have that $\widetilde{H}_n(S^n) \xrightarrow{\cong} H_n(S^n, \operatorname{im}\partial_2^n) \xleftarrow{\cong} H_n(\operatorname{im}\Delta_1^n, \partial\operatorname{im}\Delta_1^n)$ where $\Delta_1^n - \Delta_2^n \mapsto \Delta_1^n \leftarrow\!\shortmid i_n$. $\qquad\square$

Definition. Let $f : S^n \to S^n$ be a map, inducing the endomorphism $f_* : \widetilde{H}_n(S^n) \cong \mathbb{Z} \to \widetilde{H}_n(S^n) \cong \mathbb{Z}$. Then $f_*(g) = \alpha g$ for some $\alpha \in \mathbb{Z}$. We call such an α the *degree of* f, written as $\deg f$.

Proposition 15.

1. $\deg \mathbb{1}_{S^n} = 1$.

2. If $f : S^n \to S^n$ is not surjective, then $\deg f = 0$.

    Proof. Let $x \in S^n \setminus \operatorname{im} f$. Since $S^n \setminus \{x\} \cong \mathbb{R}^n$, we have that

$$\widetilde{H}_n(S^n) \xrightarrow{\;f_*\;} \widetilde{H}_n(S^n)$$

$$\underbrace{\widetilde{H}_n(S^n \setminus \{x\})}_{0}$$

$\qquad\square$

3. If $f \simeq g$, then $\deg f = \deg g$ since $f_* = g_*$.

4. By functorality, we get $\deg fg = \deg f \cdot \deg g$.

    Corollary 18. If f is a homotopy equivalence, then $\deg f = \pm 1$.

5. Define the map $i_k : S^n \to S^n$ by $(x_0, \ldots, x_n) \mapsto (x_0, \ldots, -x_k, \ldots, x_n)$. Then $\deg i_k = -1$.

Proof. Recall that $\Delta_1^n - \Delta_2^n$ generates $\widetilde{H}_n(S^n)$. Situate things so that $\partial\Delta_1^n = \partial\Delta_2^n$ is in the hyperplane $x_k = 0$. Then i_k fixes both $\partial\Delta_1^n$ and $\partial\Delta_2^n$ and interchanges the two hemispheres. Hence $i_k(\Delta_1^n - \Delta_2^n) = \Delta_2^n - \Delta_1^n$. $\qquad\square$

6. Let $i : S^n \to S^n$ be the antipodal map. Then $\deg i = (-1)^{n+1}$ since $i = i_0 \circ i_1 \circ \cdots \circ i_n$.

7. Suppose that $f : S^n \to S^n$ has no fixed point. Then $\deg f = (-1)^{n+1}$.

   Proof. If $f(x) \neq x$ for every $x \in S^n$, then the line segment $(1-t)f(x) - tx$ never passes through the origin. Therefore, the maps
   $$H_t = \frac{(1-t)f(x) - tx}{|(1-t)f(x) - tx|}$$
   define a homotopy between f and the antipodal map i. $\qquad\square$

Note 30. Let $f : S^n \to S^n$ and $x \in S^n$ such that $f^{-1}(x) = \{x_1, \ldots, x_m\}$. Let $U_1, \ldots, U_m$ be pairwise disjoint neighborhoods of $x_1, \ldots, x_m$, respectively, where we can find a neighborhood V of x such that each U_i is mapped by f into V. Then $f(U_i \setminus \{x_i\}) \subset V \setminus \{x\}$. For each $i = 1, \ldots, m$, we have a commutative diagram

$$
\begin{array}{ccc}
H_n(U_i, U_i \setminus \{x_i\}) & \xrightarrow{\quad f_* \quad} & H_n(V, V \setminus \{x\}) \\
\downarrow{\scriptstyle k_i} & & \downarrow{\scriptstyle \cong} \\
H_n(S^n, S^n \setminus \{f^{-1}(x)\}) & \xrightarrow{f_*} & H_n(S^n, S^n \setminus \{x\}) \\
\uparrow{\scriptstyle j} & & \uparrow{\scriptstyle \cong} \\
H_n(S^n) & \xrightarrow{\quad f_* \quad} & H_n(S^n)
\end{array}
$$

with $H_n(S^n, S^n \setminus \{x_i\}) \xleftarrow{p_i}$ on the left via the isomorphisms.

where the two upper isomorphisms come from excision and the two lower isomorphisms come from the LES of Corollary 10. Therefore, the homomorphism $f_* : H_n(U_i, U_i \setminus \{x_i\}) \to H_n(V, V \setminus \{x\})$ can be viewed as a homomorphism $f_* : \mathbb{Z} \to \mathbb{Z}$, so that $f_*(g) = \alpha g$ for some $\alpha \in \mathbb{Z}$. We call α the *local degree of f at x*, written as $\deg_{x_i} f$.

Lemma 31. $\deg f = \sum_{i=1}^m \deg_{x_i} f$.

Proof. By excision, we get

$$H_n(S^n, S^n \setminus f^{-1}(x)) \cong H_n\left(\coprod_{i=1}^m U_i, \coprod_{i=1}^m U_i \setminus \{x_i\}\right) \cong \bigoplus_{i=1}^m H_n(U_i, U_i \setminus \{x_i\}).$$

By the naturality of excision, we see that k_i corresponds to the i-th inclusion map and that p_i corresponds to the i-th projection map. By a straightforward diagram chase, we are done. $\qquad\square$

3.7 Lecture 15

Lemma 32. Let X be a CW-complex with skeleta X^n.

1. $H_k(X^n, X^{n-1}) = \begin{cases} 0 & k \neq n \\ \mathbb{Z}[n\text{-cells of } X] & k = n \end{cases}$.

2. $H_k(X^n) = 0$ when $k > n \geq 0$. In particular, $H_k(X) = 0$ when $k > \dim X$.

3. The inclusion $i : X^n \to X$ induces an isomorphism $i_* : H_k(X^n) \xrightarrow{\cong} H_k(X)$ when $k < n$.

Proof.

1. Since (X^n, X^{n-1}) is a good pair, we see that
$$H_k(X^n, X^{n-1}) \cong \widetilde{H}_k(X^n/X^{n-1}) \cong \widetilde{H}_k\Big(\bigvee_{n\text{-cells of X}} S^n\Big).$$

35

2. Assume that $k > n$. We have a LES

$$\cdots \longrightarrow \underbrace{H_{k+1}(X^n, X^{n-1})}_{0} \longrightarrow H_k(X^{n-1}) \longrightarrow H_k(X^n) \longrightarrow \underbrace{H_k(X^n, X^{n-1})}_{0} \longrightarrow \cdots .$$

Hence the map $H_k(X^{n-1}) \to H_k(X^n)$ is an isomorphism. From this we get a chain of isomorphisms

$$H_k(X^0) \xrightarrow{\cong} H_k(X^1) \xrightarrow{\cong} \cdots \xrightarrow{\cong} H_k(X^{k-1})$$

induced by inclusion. We are done because $H_k(X^0) = 0$.

3. If $k < n$, then the LES from part 2 produces a chain of isomorphisms

$$H_k(X^n) \cong H_k(X^{n+1}) \cong H_k(X^{n+2}) \cong \cdots .$$

Any $c \in C_k(X)$ has compact image and thus intersects at most finitely many cells of X. Thus, $[c] \in H_k(X^m)$ for some $m > k$. By our chain of isomorphisms, it follows that $[c] = [\tilde{c}]$ for some $[\tilde{c}] \in H_k(X^n)$. This proves that i_* is surjective. Moreover, if $[ic] = 0$ in $H_k(X)$, then there exists $m > n$ such that $c = \partial\tilde{c}$ for some chain $\tilde{c}$ in X^m. By out chain of isomorphism, it follows that $[c] = 0$ in $H_k(X^n)$. This proves that i_* is surjective.

$\square$

Definition. (Cellular homology) Let X be a CW-complex. Consider the three pairs (X^{n+1}, X^n), (X^n, X^{n-1}), and (X^{n-1}, X^{n-2}). We have a commutative diagram

where $d_n := j_{n-1}\partial_n$, called a *cellular boundary map*. It is clear that $d^2 = 0$, so that the horizontal row is a chain complex $(H_n(X^n, X^{n-1}), d_n)$. This gives rise to the *cellular homology of* X, written as $H_*^{CW}(X)$.

Theorem 15. For any CW-complex X, $H_n^{CW}(X) \cong H_n(X)$.

Proof. Note that $H_n(X) \cong \left. H_n(X^n) \middle/ \operatorname{im}\partial_{n+1} \right.$. Since j_n is injective,

$$\operatorname{im} d_{n+1} = \operatorname{im} j_n\partial_{n+1} = j_n(\operatorname{im}\partial_{n+1}) \cong \operatorname{im}\partial_{n+1}$$

. Since j_{n-1} is injective as well, we get

$$H_n(X^n) \cong j_n(H_n(X^n)) = \operatorname{im} j_n = \ker\partial_n = \ker d_n.$$

Thus, $j_n : H_n(X^n) \xrightarrow{\cong} \ker d_n$ such that $j_n(\operatorname{im}\partial_{n+1}) = \operatorname{im} d_{n+1}$, which implies that

$$\left. H_n(X^n) \middle/ \operatorname{im}\partial_{n+1} \right. \cong \left. \ker d_n \middle/ \operatorname{im} d_{n+1} \right. = H_n^{CW}(X).$$

$\square$

Corollary 19. If X is connected and contains only one 0-cell, then $d_1 : H_1(X^1, X^0) \to H_0(X^0)$ is the zero map.

Corollary 20. If X is a CW-complex with no n-cells, then $H_n(X) = 0$.

Example 30. Recall that $\mathbb{CP}^n = e^0 \cup e^2 \cup e^4 \cup \cdots \cup e^{2n}$. Hence each map $d_i = 0$, so that $H_k^{CW}(\mathbb{CP}^n) \cong H_k(X^k, X^{k-1})$. Therefore,

$$H_k(\mathbb{CP}^n) = \begin{cases} \mathbb{Z} & k \text{ even and } k \leq 2n \\ 0 & \text{otherwise} \end{cases}.$$

Proposition 16. (Cellular boundary formula) Let X be a CW-complex and $n > 1$. Let $d_{\alpha\beta}$ denote the degree of the composition

$$S_\alpha^{n-1} \xrightarrow{\varphi_\alpha} X^{n-1} \xrightarrow{q_\beta q} S_\beta^{n-1}$$

where φ_α denotes the attaching map of e_α^n, $q : X^{n-1} \to {}^{X^{n-1}}\!/X^{n-2}$ denotes the quotient map, and $q_\beta : {}^{X^{n-1}}\!/X^{n-2} \to S_\beta^{n-1}$ denote the map collapsing $X^{n-1} \setminus e_\beta^{n-1}$ to a point. Then

$$d_n(e_\alpha^n) = \sum_\beta d_{\alpha\beta} e_\beta^{n-1}.$$

Note that his summation contains only finitely many terms since φ_α has compact image and thus intersects only finitely cells e_β^{n-1}.

Proof. Let $\Delta_{\alpha\beta} := q_\beta q \varphi_\alpha$. Then we have a commutative diagram

$$
\begin{array}{ccccc}
H_n(D_\alpha^n, \partial D_\alpha^n) & \xrightarrow{\partial} & \widetilde{H}_{n-1}(\partial D_\alpha^n) & \xrightarrow{\Delta_{\alpha\beta*}} & \widetilde{H}_{n-1}(S_\beta^{n-1}) \\
\downarrow{\scriptstyle \Phi_{\alpha*}} & & \downarrow{\scriptstyle \varphi_{\alpha*}} & & \uparrow{\scriptstyle q_{\beta*}} \\
H_n(X^n, X^{n-1}) & \xrightarrow{\partial_n} & \widetilde{H}_{n-1}(X^{n-1}) & \xrightarrow{q_*} & \widetilde{H}_{n-1}(X^{n-1}/X^{n-2}) \\
& \searrow{\scriptstyle d_n} & \downarrow{\scriptstyle j_{n-1}} & & \downarrow{\scriptstyle \cong} \\
& & H_{n-1}(X^{n-1}, X^{n-2}) & \xrightarrow{\cong} & H_{n-1}(X^{n-1}/X^{n-2}, X^{n-2}/X^{n-2})
\end{array}
$$

The map $\Phi_{\alpha\beta*}$ sends any generator $[D_\alpha^n]$ to the generator e_α^n. From this we se that

$$d_n(e_\alpha^n) = j_{n-1} \varphi_{\alpha*} \partial [D_\alpha^n].$$

Also, the map $q_{\beta*}$ is precisely the projection map onto the copy of $\mathbb{Z}$ corresponding to the basis element e_β^{n-1}. A simple diagram chase yields our desired formula. $\square$

Example 31.

1. The closed orientable surface S_g of genus g has one 0-cell, $2g$ 1-cells, and one 2-cell. Thus, we get the cellular chain complex

$$0 \longrightarrow \mathbb{Z} \xrightarrow{d_2} \mathbb{Z}^{2g} \xrightarrow{d_1} \mathbb{Z} \longrightarrow 0 .$$

We know that $d_1 = 0$ because S_g is connected and has exactly one 0-cell. Moreover, the maps $\Delta_{\alpha\beta}$ are homotopic to constant maps, which implies that $d_2 = 0$. It follows that

$$H_n(S_g) \cong \begin{cases} \mathbb{Z} & n \in \{0, 2\} \\ \mathbb{Z}^{2g} & n = 1 \\ 0 & \text{otherwise} \end{cases}.$$

2. Recall that $\mathbb{RP}^n = e^0 \cup e^1 \cup \cdots \cup e^n$ with attaching maps the two-sheeted covering projections $\varphi : S^{k-1} \to \mathbb{RP}^{k-1}$. If $q : \mathbb{RP}^{k-1} \to \mathbb{RP}^{k-1}/\mathbb{RP}^{k-2} = S^{k-1}$ denotes the quotient map, then the composition φq is a homeomorphism when restricted to each of the two components of $S^{k-2} \setminus S^{k-1}$. Note that these two homeomorphisms are obtained from each other by precomposing with the antipodal map $S^{k-1} \to S^{k-1}$, which has degree $(-1)^k$. Therefore, $\deg q\varphi = \deg(\mathbb{1}) + \deg(-\mathbb{1}) = 1 + (-1)^k$ by our local-degree formula. It follows that

$$0 \longrightarrow \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \cdots \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \longrightarrow 0 \qquad n \text{ even}$$

$$0 \longrightarrow \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{2} \cdots \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \longrightarrow 0 \qquad n \text{ odd.}$$

Hence

$$H_k(\mathbb{RP}^n) \cong \begin{cases} \mathbb{Z} & k = 0 \text{ or } k = n \text{ odd} \\ \mathbb{Z}/2 & 0 < k < n, \ k \text{ odd} \\ 0 & \text{otherwise} \end{cases}.$$

3. Let $m > 1$ be an integer and $l_1, \ldots, l_n$ be relatively prime to m. Let ρ be the action of $\mathbb{Z}/m$ on $S^{2n-1} \subset \mathbb{C}$ generated by the homeomorphism

$$(z_1, \ldots, z_n) \mapsto (e^{\frac{2\pi i l_1}{m}} z_1, \ldots, e^{\frac{2\pi i l_n}{m}} z_n).$$

The orbit space $S^{2n-1}/\mathbb{Z}_m$ is called the *lens space* $L := L_m(l_1, \ldots, l_n)$. Note that the projection $S^{2n-1} \to L$ is a covering space since ρ is free.

Definition.

1. Let G be a finitely generated abelian group. We can write G uniquely as $\mathbb{Z}^m \times T_1 \times \cdots \times T_s$ where each T_i is a finite cyclic group. Define $\operatorname{rank} G = m$.

2. Let X be a space whose singular chain complex is finite. The *Euler characteristic* $\chi(X)$ *of* X is $\sum_n (-1)^n \operatorname{rank} H_n(X)$, which is a finite sum by Corollary 19.

Note 31. Let (C_*, d) be a chain complex of finitely generated abelian groups. The induced homology groups H_* are finitely generated abelian groups as well.

Exercise 6. If $0 \to A \to B \to C \to 0$ is an exact sequence of finitely generated abelian groups, then $\operatorname{rank} B = \operatorname{rank} A + \operatorname{rank} C$.

Lemma 33. Let $(C_*(X), d)$ be a finite singular chain complex. Then $\chi(X) = \sum_n (-1)^n \operatorname{rank} C_n$.

Proof. We can write out chain complex as

$$0 \longrightarrow C_k \xrightarrow{d_k} C_{k-1} \xrightarrow{d_{k-1}} \cdots \longrightarrow C_1 \xrightarrow{d_1} C_0 \longrightarrow 0 .$$

We have short exact sequences $0 \to Z_n \to C_n \to B_{n-1} \to 0$ and $0 \to B_n \to Z_n \to H_n \to 0$. This shows that $\operatorname{rank} C_n = \operatorname{rank} Z_n + \operatorname{rank} B_{n-1}$ and $\operatorname{rank} Z_n = \operatorname{rank} B_n + \operatorname{rank} H_n$. It follows that

$$\operatorname{rank} C_n = \operatorname{rank} B_n + \operatorname{rank} H_n + \operatorname{rank} B_{n-1}.$$

Hence $\sum_n (-1)^n \operatorname{rank} C_n(X) = \sum_n (-1)^n \operatorname{rank} H_n(X)$. $\qquad \square$

Corollary 21. Let X be a finite CW-complex. Then

$$\chi(X) = \sum_n (-1)^n c_n$$

where c_n denotes the number of n-cells of X.

3.8 Lecture 16

Theorem 16. Let X be a path connected space. There exists a surjective map $h : \pi_1(X) \to H_1(X)$ with $\ker h = [\pi_1(X), \pi_1(X)]$. In this case,
$$\pi_1(X)_{ab} \cong H_1(X).$$

Proof. Define $h : \pi_1(X) \to H_1(X)$ by $\gamma \mapsto \sigma_\gamma$ where $\sigma_\gamma(t) = \gamma(t)$. $\qquad\qquad\square$

Example 32. We get surjective maps $\pi_1(S^1 \vee S^1) \cong \mathbb{F}_2 \to H_1(S^1 \vee S^1) \cong \mathbb{Z}^2$ and $\pi_1(S_g) \to H_1(S_g) \cong \mathbb{Z}^{2g}$.

Definition. Let R be a (unital) ring. Let M be an R-module and N be a right R-module. The *tensor product* $(N \otimes_R M, \psi)$ consists of an R-module $N \otimes_R M$ and a R-bilinear map $\psi : N \times M \to N \otimes_R M$ such that for any R-bilinear map $f : N \times M \to F$, there is a unique R-linear map $g : N \otimes_R M \to F$ such that $g\psi = f$.

Proposition 17.

1. $N \otimes_R R \cong N$.

2. $\mathbb{Z}^n \otimes_{\mathbb{Z}} \mathbb{Z}^m \cong \mathbb{Z}^{nm}$.

3. $\mathbb{Z}/n \otimes_{\mathbb{Z}} \mathbb{Z}/m \cong \mathbb{Z}/(n, m)$.

Definition. (Homology with coefficients) Let G be an abelian group and X be a space. Define $(C_*(X; G), \partial) = (C_* \otimes_{\mathbb{Z}} G, \partial \otimes \mathbb{1})$ and $H_*(X; G) = H_*(C_*(X; G))$.

Note 32. It it *not* true that if C_* is a chain complex, then $H_*(C_* \otimes G) \cong H_*(C_*) \otimes G$.

Definition.

Remark 17.

1. Let M be an R-module. Consider the functor $N \mapsto N \otimes_R M$ from $R^{\mathrm{op}} - \mathbf{Mod}$ to $\mathbf{Ab}$. This is right exact and thus has *left derived functors* denoted by $\mathrm{Tor}_i^R(-, M)$. Specifically, from any projective resolution $\cdots \to P^2 \to P^2 \to P^0 \to N \to 0$ in $R^{\mathrm{op}} - \mathbf{Mod}$, construct C_* the chain complex

$$\cdots \to P^2 \otimes_R M \to P^1 \otimes_R M \to P^0 \otimes_R M \to 0.$$

   Then $\mathrm{Tor}_i^R(N, M) = H_i(C_*)$.

   Note 33. The definition of Tor_i^R is independent of the choice of projective resolution.

2. Consider a functor F from $\mathbf{Top}$. It may be that FX depends on more than the homotopy type of X. To "extend" F to the homotopy category, we replace X by an equivalent cofibrant space or CW-complex. Since projective modules are precisely the cofibrant spaces in $\mathbf{Mod}$, we see that

$$\cdots \to P^1 \to P^0$$

   is a *cofibrant replacement* of N. This is why we remove N when constructing our new chain complex C_* above.

Example 33.

1. We have a free resolution $0 \to \mathbb{Z} \xrightarrow{n} \mathbb{Z} \to \mathbb{Z}/n \to 0$ of $\mathbb{Z}/n$ over $\mathbb{Z}$, from which we form the complex

$$\mathbb{Z} \otimes \mathbb{Z} \xrightarrow{n \otimes \mathbb{1}} \mathbb{Z} \otimes \mathbb{Z} \to 0.$$

   This is precisely $\mathbb{Z} \xrightarrow{n} \mathbb{Z} \to 0$. Hence

$$\mathrm{Tor}_i^{\mathbb{Z}}(\mathbb{Z}/n, \mathbb{Z}) \cong \begin{cases} \mathbb{Z}/n\mathbb{Z} & i = 0 \\ 0 & i > 0 \end{cases}.$$

2. We have a trivial free resolution $0 \to \mathbb{Z} \to \mathbb{Z} \to 0$ of $\mathbb{Z}$ over $\mathbb{Z}$. From this we form the complex

$$0 \to \mathbb{Z} \otimes \mathbb{Z}/n \to 0,$$

which becomes $0 \to \mathbb{Z}/n \to 0$. Hence

$$\mathrm{Tor}_i^{\mathbb{Z}}(\mathbb{Z}, \mathbb{Z}/n) \cong \begin{cases} \mathbb{Z}/n & i = 0 \\ 0 & i > 0 \end{cases}.$$

3. We have a free resolution $0 \to \mathbb{Z} \xrightarrow{n} \mathbb{Z} \to \mathbb{Z}/n \to 0$ of $\mathbb{Z}/n$ over $\mathbb{Z}$, from which we form the complex

$$\mathbb{Z} \otimes \mathbb{Z}/m \xrightarrow{n \otimes \mathbb{1}} \mathbb{Z} \otimes \mathbb{Z}/m \to 0.$$

This is precisely $\mathbb{Z}/m \xrightarrow{n} \mathbb{Z}/m \to 0$. Hence

$$\mathrm{Tor}_i^{\mathbb{Z}}(\mathbb{Z}/n, \mathbb{Z}/m) \cong \begin{cases} \ker(\mathbb{Z}/m \xrightarrow{n} \mathbb{Z}/m) \cong \mathbb{Z}/(n, m) & i = 1 \\ 0 & i \neq 1 \end{cases}.$$

Remark 18. Suppose that (C_*, ∂) is a chain complex and that $0 \to P^1 \to P^0 \to H \to 0$ is a projective resolution. For each $n \in \mathbb{N}$, we get a (non-canonical) split short exact sequence

$$0 \to H_n(X) \otimes G \to H_n(X; G) \to \mathrm{Tor}_1(H_{n-1}(X), G) \to 0,$$

called the *universal coefficient sequence (for homology)*. Therefore,

$$H_n(X; G) \cong (H_n(X) \otimes G) \oplus \mathrm{Tor}_1(H_{n-1}(X), G).$$

Example 34. Let $X = \mathbb{RP}^n$ and $G = \mathbb{Z}/2$. By the universal coefficient sequence, it is straightforward to show that

$$H_n(\mathbb{RP}^n; \mathbb{Z}/2) \cong \mathbb{Z}/2$$

for every n. For example, we have that

$$
\begin{aligned}
H_1(\mathbb{RP}^n, \mathbb{Z}/2) \cong H_1(\mathbb{RP}^n; \mathbb{Z}/2) &\cong (H_1(X) \otimes \mathbb{Z}/2) \oplus \mathrm{Tor}_1(H_0(\mathbb{RP}^n), \mathbb{Z}/2) \\
&\cong (\mathbb{Z}/2 \otimes \mathbb{Z}/2) \oplus \mathrm{Tor}_1(\mathbb{Z}, \mathbb{Z}/2) \\
&\cong \mathbb{Z}/2 \oplus 0 \\
&\cong \mathbb{Z}/2.
\end{aligned}
$$

3.9 Lecture 17

Definition. We say that a space M is an *n-dimensional manifold* if it is Hausdorff and for any $x \in M$, there exist an open set $U \ni x$ and a homeomorphism $U \to \mathbb{R}^n$. In this case, we call U a *coordinate ball around x*.

Definition. Let X be an n-manifold and $x \in X$. Let U be a coordinate ball around x. Then

$$
\begin{aligned}
H_k(X, X \setminus x) &\cong H_k(U, U \setminus x) \\
&\cong \widetilde{H}_{k-1}(U \setminus x) \\
&\cong \widetilde{H}_{k-1}(S^{n-1}) \cong \begin{cases} 0 & k \neq n \\ \mathbb{Z} & k = n \end{cases}.
\end{aligned}
$$

There are precisely two generators of $\widetilde{H}_n(U, U \setminus x)$, a choice α_x of which is called a *local orientation of X at x*.

Lemma 34. Given $\alpha_x \in H_n(X, X \setminus x)$, there exist a neighborhood U of x and $\alpha_U \in H_n(X, X \setminus U)$ such that $j_x^U(\alpha_U) = \alpha_x$ where $j_x^U : H_n(X, X \setminus U) \to H_n(X, X \setminus x)$.

Proof. Let c be a relative cycle representing α_x. Then $\operatorname{supp} \partial c \subset X \setminus x$. Let $U = X \setminus \operatorname{supp} \partial c$ and $\alpha_U = [c] \in H_n(X, X \setminus U)$. $\qquad \square$

Lemma 35. Every neighborhood W of x contains some neighborhood U of x such that for each $y \in U$, $j_y^U : H_n(X, X \setminus U) \to H_n(X, X \setminus y)$ is an isomorphism.

Proof. Let V be a coordinate neighborhood of x that is contained in W. Then there is a homeomorphism $\psi : V \to \mathbb{R}^n$. Let U be a unit ball via ψ. We get a commutative diagram

$$
\begin{array}{ccccc}
H_n(X, X \setminus U) & \xleftarrow{\cong} & H_n(V, V \setminus U) & \xrightarrow{\cong} & \widetilde{H}_{n-1}(V \setminus U) \\
{\scriptstyle j_y^U} \downarrow & & \downarrow & & \downarrow {\scriptstyle \cong} \\
H_n(X, X \setminus y) & \xleftarrow{\cong} & H_n(V, V \setminus y) & \xrightarrow{\cong} & \widetilde{H}_{n-1}(V \setminus y)
\end{array} \quad ,
$$

which shows that j_y^U is an isomorphism for any $y \in U$. $\qquad \square$

Definition. An n-manifold X is *orientable* if for any $x \in X$, we can choose a local orientation $\alpha_x \in H_n(X, X \setminus x)$ such that for any $x \in X$, we can find an open set $U \ni x$ and $\alpha_U \in H_n(X, X \setminus U)$ such that $j_y^U(\alpha_U) = \alpha_y$ for every $y \in U$. We call such a choice of local orientations *locally compatible*. If we specify the local orientations α_x, then we say that X is *oriented*.

Remark 19. Let X be an n-manifold. Any inclusion $U \subset V$ of open sets induces a map $H_n(X, X \setminus V) \to H_n(X, X \setminus U)$. Thus,
$$U \mapsto H_n(X, X \setminus U)$$
defines a presheaf $\mathcal{O}_n$ on X, called the *orientation sheaf of X*. By our last two lemmas along with excision, this is a *locally constant sheaf* in that for any $x \in X$, there is some open set $V \ni x$ such that $U \subset V \mapsto H_n(X, X \setminus U)$ is constant.

Definition. Let $x \in X$. The *stalk of $\mathcal{O}_n$ at x* is
$$\varinjlim_{U \ni x} H_n(X, X \setminus U).$$

Note 34. The stalk of $\mathcal{O}_n$ at x is isomorphic to $H_n(X, X \setminus x) \cong \mathbb{Z}$.

Note 35. Let X be an n-manifold.

1. Let $X^{or} := \{(x, \alpha) \mid x \in X, \ \alpha \in H_n(X, X \setminus x) = \langle \alpha \rangle\}$. Topologize this by letting a basic neighborhood of (x, α) look like
$$\widetilde{U} := \{(y, j_y^U(\alpha_U)) \mid y \in U\}$$
where U is a neighborhood of x such that j_y^U is an isomorphism for each $y \in U$.

   The projection map $p : X^{or} \to X$ is two-to-one and thus a two-fold covering of X, called the *orientation cover*. A (continuous) section $o : X \to X^{or}$ of p is an orientation of X.

   Note that X^{or} has a canonical orientation $(x, \alpha_x) \mapsto \alpha_x$ since α_x generates
$$H_n(X^{or}, X^{or} \setminus (x, \alpha_x)) \cong H_n(\widetilde{U}, \widetilde{U} \setminus (x, \alpha_x)) \cong H_n(X, X \setminus x).$$

Proposition 18. If X is connected, then X is orientable if and only if X^{or} has precisely two components.

Corollary 22. If X is simply connected, then X is orientable.

Proof. If X is simply connected, then it has no subgroup of index 2. Since every nontrivial two-sheeted covering space of X corresponds to an index-2 subgroup of $\pi_1(X)$, it follows that p is trivial. Thus, $X^{or} \cong X \coprod X$. $\qquad \square$

2. Let $X^{Zor} := \{(x, \alpha) \mid x \in X, \ \alpha \in H_n(X, X \setminus x)\}$. Topologize this by letting a basic neighborhood of (x, α) look like

$$\widetilde{U} := \{(y, j_y^U(\alpha_U)) \mid y \in U\}$$

where U is a basic neighborhood of x but j_y^U need not be an isomorphism.

The projection $p : X^{Zor} \to X$ is an $\aleph_0$-sheeted covering projection, with each sheet corresponding to an element of $\mathbb{Z}$. Let $\Gamma(A)$ denote the space of sections $s : A \to X^{Zor}$ over an open subset $A \subset X$. Note that $\Gamma(A)$ inherits an abelian group operation from $\mathbb{Z}$.

Theorem 17. Let X be an n-manifold and $A \subset X$ be compact.

(a) $H_q(X, X \setminus A) = 0$ when $q > n$.

(b) Define the group homomorphism $j_A : H_n(X, X \setminus A) \to \Gamma(A)$ by $\alpha \mapsto (x \mapsto \alpha_x)$ where $\alpha_x = j_x^A(\alpha)$. This is an isomorphism.

Proof. First of all, note that the case where $A = \emptyset$ is obvious. There are four other cases to consider.

Step 1: Suppose that our theorem is true of the compact sets A, B, and $A \cap B$ in X. Then our theorem is true from $A \cap B$.

Proof. Consider the MV sequence

$$H_{q+1}(X, X \setminus (A \cap B)) \to H_q(X, X \setminus (A \cup B)) \to H_q(X, X \setminus A) \oplus H_q(X, X \setminus B) \to H_q(X, X \setminus (A \cap B)).$$

If $q > n$, then our hypotheses immediately imply that $H_q(X, X \setminus (A \cup B)) = 0$. This verifies part (a). For part (b), we can extend our last sequence to a commutative diagram with exact rows

$$
\begin{array}{ccccccc}
0 & \longrightarrow & H_n(X, X \setminus (A \cup B)) & \longrightarrow & H_n(X, X \setminus A) \oplus H_n(X, X \setminus B) & \longrightarrow & H_n(X, X \setminus (A \cap B)) \\
& & \downarrow{\scriptstyle j_{A \cup B}} & & \downarrow{\scriptstyle j_A \oplus j_B (\cong)} & & \downarrow{\scriptstyle j_{A \cap B} (\cong)} \\
0 & \longrightarrow & \Gamma(A \cup B) & \longrightarrow & \Gamma(A) \oplus \Gamma(B) & \longrightarrow & \Gamma(A \cap B)
\end{array}
$$

By the five lemma, it follows that $j_{A \cup B}$ is an isomorphism. $\qquad\square$

Step 2: Suppose that A is contained in a coordinate chart U evenly covered by $p : X^{Zor} \to X$. Also, suppose that we can write A as a finite union of parallelepipeds $A_1, A_2, \ldots, A_m$ such that each face of A_i is parallel to some coordinate axis. Then our theorem holds for A.

Proof. We apply induction on m. If $m = 1$, it's enough to observe that

$$H_q(X, X \setminus A) \cong H_q(U, U \setminus A)$$
$$\cong \widetilde{H}_{q-1}(U \setminus A) \cong \widetilde{H}_{q-1}(S^{n-1}).$$

Suppose, inductively, that our theorem is true of $m \in \mathbb{N}$. Let $B = A_1 \cup A_2 \cup \cdots \cup A_m$. By our IH, our theorem holds for B and A_{m+1}. Further,

$$B \cap A_{m+1} = (A_1 \cap A_{m+1}) \cup \cdots \cup (A_m \cap A_{m+1}).$$

Each factor of this union is a parallelepiped where each face is parallel to some coordinate axis. By induction, it follows that our theorem holds for $B \cap A_{m+1}$. By Step 1, it holds for $B \cup A_{m+1}$ as well. $\qquad\square$

Step 3: Suppose that A is contained in a coordinate chart U evenly covered by $p : X^{Zor} \to X$. Then our theorem holds for A.

Proof. Let $s \in \Gamma(A)$. <mark>Without loss of generality</mark>, we may assume that im s is contained in a single sheet over U. Thus, s extends to some $s^* \in \Gamma(U)$.

For each $x \in A$, find some parallelepiped $P_x \subset U$ with $x \in \text{Int } P_x$ such that each wall of P_x is parallel to some coordinate axis. Let $A' = \bigcup_{x \in A} P_x$. Since A is compact, we may write $A' = P_{x_1} \cup \cdots \cup P_{x_k}$. We have a commutative square

$$
\begin{array}{ccc}
H_n(X, X \setminus A') & \xrightarrow{j_{A'}} & \Gamma(A') \\
\downarrow & & \downarrow \\
H_n(X, X \setminus A) & \xrightarrow{j_A} & \Gamma(A)
\end{array} .
$$

Note that the right arrow is surjective. By Step 2, we have that $j_{A'}$ is an isomorphism. It follows that j_A is surjective.

Let $c \in H_q(X.X \setminus A)$ with $q \geq n$. If $q = n$, suppose that $j_A(c) = 0$. <mark>We must show that $c = 0$.</mark> Let z denote a relative cycle representing c, so that $\partial z \subset X \setminus A$. Then $V := X \text{ cl}(\partial z)$ is an open set containing A. Let $c' := [z]$ in $H_q(X, X \setminus V)$. If $q = n$, then $j_x^V(c') = j_x^A(c) = 0$ for each $x \in A$.. Hence there exists an open set $A \subset V' \subset V$ such that $j_x^V(c') = 0$ for each $x \in V'$. Now, construct A' as before, so that $j_{A'}(c') = 0$ by Step 2. It follows that $c = j_A^{A'}(j_{A'}^V(c')) = 0$. $\square$

Step 4: Suppose that A is compact. Then our theorem holds for A.

Proof. Note that A can be written as a union of coordinate charts $U_1, U_2, \ldots, U_m$ that are evenly covered by p. Thus, we can apply induction on m. Our base case follows directly from Step 3, and our inductive step follows by a similar argument to Step 2. $\square$

$\square$

Corollary 23. Let X be an n-manifold with $A \subset X$ compact. Let $x \mapsto \alpha_x \in H_n(X, X \setminus x; R)$ be an R-orientation on X. Then there exists an element $\alpha_A \in H_n(M, M \setminus A; R)$ whose image in $H_n(X, X \setminus x; R)$ equals α_x for every $x \in A$.

Corollary 24. If X is a closed n-manifold, then $H_q(X) = 0$ for any $q > n$.

Corollary 25. If X is a closed connected orientable manifold, then

$$
H_n(X) \cong \Gamma(X) \cong \mathbb{Z}.
$$

In this case, we call a generator $[X]$ of $H_n(X)$ a *fundamental* or *orientation class for X*. Note that $[X]$ is precisely a section of $X^{or} \to X$ and thus determines an orientation of X. We denote the opposite orientation to this by $-[X]$.

Note 36. If X is not orientable, then $H_n(X) = 0$.

Remark 20. Let $M \subset X$ be a closed oriented n-submanifold. Then $i_*[M] \in H_n(X)$. But it is not true that any homology class in $H_n(X)$ can be represented by the fundamental class for a submanifold.

Definition. Let X be any space. Define the *open cone on X* as

$$
C^0 X = \left. [0, 1) \times X \middle/ (x, 0) \sim (x', 0) \right. .
$$

Definition. Let X be a paracompact Hausdorff space. Let

$$
X = X_n \supset X_{n-1} \supset X_{n-2} \supset \cdots \supset X_1 \supset X_0 \supset X_{-1} = \emptyset
$$

be a filtration of X such that for any $x \in X_i \setminus X_{i-1}$, there exist
- a neighborhood N of x,

- a compact $(n-i-1)$-dimensional stratified space L

$$L = L_{n-i-1} \supset L_{n-i-2} \supset \cdots \supset L_0,$$

and

- a homeomorphism $\varphi : \mathbb{R}^i \times C^0 L \to N$ that restricts to a homeomorphism $R^i \times C^0 L_j \to N \cap X_{i+j+1}$.

We call $S_i \coloneqq X_i \setminus X_{i-1}$ the i-dimensional stratum of X and L a link of this stratum.

Note 37. The i-dimensional stratum of X is an i-manifold.

Example 35.

1. Complex algebraic varieties.

2. Complex analytic varieties.

3. Real algebraic varietes.

4. Real analytic varieties.

5. Real semi-algebraic varieties.

6. Subanalytic spaces.

7. Triangulated spaces.

Definition. An n-dimensional stratified space is called a *pseudomanifold* if $S_{n-1} = \emptyset$.

Example 36.

1. Complex algebraic varieties.

2. Complex analytic varieties.

3. Triangulated spaces such that any $(n-1)$-simplex is the face of exactly two n-simplices.

Remark 21. Every homology class can be represented by a pseudomanifold.

3.10 Lecture 18

Definition. Let X be an n-manifold. Let R be a commutative ring. Note that $H_n(X, X \setminus x; R) \cong R$ for any $x \in X$. An *R-orientation of X* is a locally compatible mapping $x \mapsto u_x$ such that $(u_x) = H_n(X, X \setminus x; R)$, i.e., u_x is a unit.

Example 37. Let $R = \mathbb{Z}/2$. Then there is exactly one choice of generator of $H_n(X, X \setminus x; R)$. It's easy to show that the orientation cover of X must be X itself. This implies that any manifold has a $\mathbb{Z}/2$-orientation. It follows that $H_n(X; \mathbb{Z}/2) \cong \mathbb{Z}/2$ when X is closed and connected.

4 Cohomology

Definition. Let (C_*, ∂) be a chain complex of free abelian groups and G be an abelian group. Let

$$C_G^n := \mathrm{Hom}_{\mathbb{Z}}(C_n, G).$$

Define the *coboundary map* $\delta : C_G^n \to C_G^{n+1}$ by $(\varphi : C_n \to G) \mapsto (c \mapsto \varphi(\partial c))$. Then $\delta^2 = 0$. so that we get a *cochain complex*

$$C_G^0 \xrightarrow{\delta} C_G^1 \xrightarrow{\delta} C_G^2 \xrightarrow{\delta} \cdots \xrightarrow{\delta} C_G^k \xrightarrow{\delta} C_G^{k+1} \xrightarrow{\delta} \cdots ..$$

Define the group of *k-cocycles* as

$$Z_G^k = \ker(\delta : C_G^k \to C_G^{k+1})$$

and the group of *k-coboundaries* as

$$B_G^k = \mathrm{im}(\delta : C_G^{k-1} \to C_G^k).$$

The *k-th cohomology group of C (with coefficients in G)* is

$$H^k(C; G) = {Z_G^k}\big/{B_G^k}.$$

Note 38.

1. Let $\varphi \in Z_G^n$, so that $\delta\varphi = 0$. Then $\varphi\partial = 0$, which means that $B_n \subset \ker\varphi$. This induces a map $\tilde{\varphi} : H_n(C) \to G$. We thus have an additive map $h : \varphi \mapsto \tilde{\varphi}$.

   To see that h is well-defined, suppose that $\varphi = \delta\psi$ for some $\psi : C_{n-1} \to G$. Then $\varphi = \psi\partial$, which implies that φ vanishes on Z_n. Hence $\tilde{\varphi} = 0$. This proves that $h : H^n(C; G) \to \mathrm{Hom}_{\mathbb{Z}}(H_n(C); G)$ is well-defined.

2. Let A and B be abelian groups. There is a surjective map $f : F_0 \to A$ where F_0 is a free abelian group. Form a free resolution F of A

   $$0 \to F_1 \xrightarrow{i} F_0 \xrightarrow{f} A \to 0$$

   where $F_1 := \ker f$. Consider the induced map $i^* : \mathrm{Hom}(F_0, B) \to \mathrm{Hom}(F_1, B)$. Let

   $$\mathrm{Ext}(A, B) := H^1(F; B) = \mathrm{coker}\, i^*,$$

   which is independent of our choice of F.

Example 38.

1. If A is free, then $\mathrm{Ext}(A, B) = 0$.

2. If $A = \mathbb{Z}/n$, then consider the free resolution $0 \to \mathbb{Z} \xrightarrow{n \cdot -} \mathbb{Z} \to \mathbb{Z} \to 0$. This induces a map

   $$\mathrm{Hom}(\mathbb{Z}, B) \cong B \xrightarrow{n \cdot -} \mathrm{Hom}(\mathbb{Z}, B) \cong B,$$

   so that $\mathrm{Ext}(\mathbb{Z}/n, B) \cong B/nB$.

Theorem 18. (Universal coefficient theorem (for cohomology)) There exists a non-canonical split short exact sequence

$$0 \longrightarrow \mathrm{Ext}(H_{n-1}(C), G) \longrightarrow H^n(C; G) \xrightarrow{h} \mathrm{Hom}(H_n(C), G) \longrightarrow 0 \ .$$

Note 39.

1. Let X be a space and $C_*(X)$ our singular chain complex. Then $C^n(X; G) = \mathrm{Hom}(C_n(X), G)$. For any *singular n-cochain* φ, we have that

$$\delta\varphi(\sigma : \Delta^{n+1} \to X) = \sum_{k=0}^{n+1} (-1)^k \varphi(\sigma \restriction_{[v_0, \ldots, \hat{v}_i, \ldots, v_{n+1}]}).$$

2. Any map $f : X \to Y$ of spaces induces a chain map $f_* : C_*(X) \to C_*(Y)$, which in turn induces a cochain map $f^* : C^*(Y; G) \to C^*(X; G)$ such that $\delta f = f \delta$. We thus get a map on cohomology $f^* : H^n(Y; G) \to H^n(X; G)$, called the *pullback of f*.

3. **(Reduced cohomology)** Define the map $f : G \to C^n(X; G)$ by $g \mapsto c_g$ where c_g denotes the constant map at g. Let $\widetilde{C}^*(X; G) := \operatorname{coker} f$, thereby defining $\widetilde{H}^*(X; G)$.

   Then $\widetilde{H}^n(X; G) = H^n(X; G)$ when $n > 0$. Note that $C^0(X; G)$ is precisely the group of functions $X \to G$. For any function $\varphi : X \to G$, we have that $\delta\varphi(\sigma) = \varphi(\sigma(1)) - \varphi(\sigma(0))$ for any $\sigma \in \operatorname{Sing}_1(X)$. This shows that φ is a cocycle if and only if it is constant on each path component of X. Thus,

$$H^0(X; G) \cong \prod_{\pi_0(X)} G.$$

   It follows that $\widetilde{H}^0(X; G)$ is precisely the group of all functions $X \to G$ constant on each path component of X modulo the group of globally constant functions $X \to G$.

4. **(Relative cohomology)** Let (X, A) be a pair. Note that $C_n(X, A)$ is isomorphic to the free abelian group with basis $\{\varphi : \Delta^n \to X \mid \operatorname{im} \varphi \subset X \setminus A\}$. Applying $\operatorname{Hom}(-, G)$ to the short exact sequence $\eta : 0 \to C_n(A) \to C_n(X) \to C_n(X, A) \to 0$ yields the sequence

$$0 \longleftarrow C^n(A; G) \longleftarrow C^n(X; G) \longleftarrow C^n(X, A; G) \longleftarrow 0.$$

   This is exact because η splits. Thus,

$$C^n(X, A; G) \cong \{\varphi : \operatorname{Sing}_n(X) \to G \mid \sigma : \Delta^n \to A \implies \varphi(\sigma) = 0\}.$$

Proposition 19.

1. **(Homotopy invariance)** If $f \simeq g$ as maps $X \to Y$, then $f^* = g^*$ as maps $H^*(Y; G) \to H^*(X; G)$.

2. **(Snake)** Let (X, A) be pair. There exists a *long exact sequence in cohomology*

$$\cdots \longrightarrow H^n(X, A) \longrightarrow H^n(X) \longrightarrow H^n(A)$$
$$H^{n+1}(X, A) \longleftarrow \longrightarrow \cdots$$

3. **(Excision)** Let $Z \subset A \subset X$ such that $\operatorname{cl} Z \subset \operatorname{Int} A$. Then $H^*(X, A; G) \cong H^*(X \setminus Z, A \setminus Z; G)$.

4. **(MV sequence)** Let $X = \operatorname{Int} A \cup \operatorname{Int} B$. Then there exists a LES

$$H^n(X) \longrightarrow H^n(A) \oplus H^n(B) \longrightarrow H^n(A \cap B)$$
$$H^{n+1}(X) \longleftarrow \longrightarrow \cdots$$

Definition. Let X be a space and R be a ring. Let $k, l \in \mathbb{N}$. Define the *cup product* $C^k(X; R) \times C^l(X; R) \overset{\smile}{\longrightarrow} C^{k+l}(X; R)$ by

$$\varphi \smile \psi(\sigma : \Delta^{k+l} \to X) = \varphi(\sigma \restriction_{[v_0, \ldots, v_k]}) \cdot_R \psi(\sigma \restriction_{v_k, \ldots, v_{k+l}}).$$

Note 40. The same definition works for relative singular cochain complexes. In general, if $f \in C^k(X, A; R)$ and $g \in C^l(X, B; R)$, then $f \smile g \in C^{k+l}(X, A \cup B; R)$.

Proposition 20. Let $\mathbb{1} \in C^0(X; R)$ denote the constant map at 1_R. Then $\mathbb{1} \smile \varphi = \varphi \smile \mathbb{1} = \varphi$.

Lemma 36. $\delta(\varphi \smile \psi) = \delta\varphi \smile \psi + (-1)^k \varphi \smile \delta\psi$.

Proof. We do the case where $\varphi, \psi \in C^1(X; R)$. If $\sigma \in \mathrm{Sing}_3(X)$, then

$$
\begin{aligned}
(\delta\varphi \smile \psi - \varphi \smile \delta\psi)(\sigma) &= \delta\varphi([v_0, v_1, v_2])\psi([v_2, v_3]) - \varphi([v_0, v_1])\delta\psi([v_1, v_2, v_3]) \\
&= \varphi([v_1, v_2])\psi([v_2, v_3]) - \varphi([v_0, v_2])\psi([v_2, v_3]) + \varphi([v_0, v_1])\psi([v_2, v_3]) \\
&\quad - \varphi([v_0, v_1])\psi([v_2, v_3]) + \varphi([v_0, v_1])\psi([v_1, v_3]) - \varphi([v_0, v_1])\psi([v_1, v_2]) \\
&= \delta(\varphi \smile \psi)(\sigma)
\end{aligned}
$$

$\square$

Corollary 26. The cup product descends to an operation

$$
H^k(X, A; R) \times H^l(X, A; R) \xrightarrow{\smile} H^{k+l}(X, A; R).
$$

4.1 Lecture 19

Example 39.

1. Let $X = S_g$. By the universal coefficient theorem, we have that

$$
0 \to \mathrm{Ext}(H_0(X), \mathbb{Z}) \to H^1(X; \mathbb{Z}) \to \mathrm{Hom}(H_1(X), \mathbb{Z}) \to 0.
$$

Since $H_0(X) \cong \mathbb{Z}$ and $H_1(X) \cong \mathbb{Z}^{2g}$, it follows that $H^1(X; \mathbb{Z}) \cong \mathbb{Z}^{2g}$.

2. Let $X = \mathbb{RP}^n$.

k	H_k	$\mathrm{Ext}(H_{k-1}, \mathbb{Z})$	$\mathrm{Hom}(H_k, \mathbb{Z})$	$H^k(X; \mathbb{Z})$	$\mathrm{Ext}(H_{k-1}, \mathbb{Z}/2)$	$\mathrm{Hom}(H_k, \mathbb{Z}/2)$	$H^k(X; \mathbb{Z}/2)$
0	$\mathbb{Z}$	0	$\mathbb{Z}$	$\mathbb{Z}$	0	$\mathbb{Z}/2$	$\mathbb{Z}/2$
1	$\mathbb{Z}/2$	0	0	0	0	$\mathbb{Z}/2$	$\mathbb{Z}/2$
2	0	$\mathbb{Z}/2$	0	$\mathbb{Z}/2$	$\mathbb{Z}/2$	0	$\mathbb{Z}/2$
3	$\mathbb{Z}/2$	0	0	0			$\mathbb{Z}/2$
4	0	$\mathbb{Z}/2$	0	$\mathbb{Z}/2$			
5	$\mathbb{Z}/2$	0	0				
6	0						
$\vdots$	$\vdots$		$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
$n-2$		$\mathbb{Z}/2$		0			
$n-1$	$\mathbb{Z}/2$	0		$\mathbb{Z}/2$			
n	$\begin{cases} \mathbb{Z} & n \text{ odd} \\ 0 & n \text{ even} \end{cases}$	$\begin{cases} \mathbb{Z}/2 & n \text{ odd} \\ 0 & n \text{ even} \end{cases}$	$\mathbb{Z}$, n odd	$\mathbb{Z}$, n odd			$\mathbb{Z}/2$, n odd

3. Let $0 \leq k \leq 2n$. Then $H_k(\mathbb{CP}^n) \cong \begin{cases} \mathbb{Z} & k \text{ even} \\ 0 & k \text{ odd} \end{cases}$.

Proposition 21. If X has torsion-free homology, then $H^n(X; \mathbb{Z}) \cong \mathrm{Hom}(H_n(X; \mathbb{Z}), \mathbb{Z})$ for every n.

Therefore,

$$
H^k(\mathbb{CP}^n; \mathbb{Z}) \cong \begin{cases} \mathbb{Z} & k \text{ even} \\ 0 & k \text{ odd} \end{cases}.
$$

Theorem 19. If R is commutative and $\varphi, \psi \in H^*(X, A; R)$, then $\varphi \smile \psi = (-1)^{|\varphi||\psi|}\psi \smile \varphi$ where $|\cdot|$ denotes the degree of a cocycle. Thus, $\smile$ is *graded commutative*.

Remark 22. But $\smile$ is not graded commutative at the chain level. By contrast, the wedge product $\wedge$ of differential forms is graded commutative at the chain level.

Example 40. Let $X = S_g$. One can show that $H_1(X)$ has $(a_1, \ldots, a_g, b_1, \ldots, b_g)$ as a basis. Since $H^1(X; \mathbb{Z}) \cong \mathrm{Hom}(H_1(X), \mathbb{Z})$ by the universal coefficient theorem, there exists a dual basis $(\alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_g)$ for $H^1(X; \mathbb{Z})$.

For each $1 \leq i \leq g$, we want to represent each α_i by a cocycle φ_i and each β_i by a cocycle ψ_i. To this end, let

$$\varphi_i(\sigma : \Delta^1 \to X) = \begin{cases} 1 & \sigma \cap \alpha_i \neq \emptyset \\ 0 & \sigma \cap \alpha_i = \emptyset \end{cases}.$$

Define ψ_i similarly. Letting $g = 2$, it is straightforward to verify that both $\delta \varphi_i$ and $\delta \psi_i$ vanish on each 2-simplex inside S_2.

Figure 7: copied from Hatcher (207)

It is also straightforward to verify that $\varphi_1 \smile \psi_1$ vanishes on each 2-simplex inside S_2 except the lower one marked by b_1, on which it equals 1. It follows that $\varphi_1 \smile \psi_1(c) = 1$ where c denotes the linear combination of the 2-chains comprising S_2 with the indicated coefficients ± 1. This shows that $[c]$ generates $H_2(X) \cong \mathbb{Z}$ and that $\varphi_1 \smile \psi_1$ represents the dual generator γ of $H^2(X; \mathbb{Z}) \cong \mathbb{Z}$. Hence $\alpha_1 \smile \beta_1 = [\gamma]$. In general, we can compute the relations

$$\alpha_i \smile \beta_j = \begin{cases} \gamma & i = j \\ 0 & i \neq j \end{cases} = -(\beta_i \smile \alpha_j)$$
$$\alpha_i \smile \alpha_j = 0$$
$$\beta_i \smile \beta_j = 0.$$

These completely determine $H^1(X; \mathbb{Z}) \times H^1(X; \mathbb{Z}) \xrightarrow{\smile} H^2(X; \mathbb{Z})$ because $\smile$ is distributive.

Definition. Let X and Y be spaces. The *external product* is the R-bilinear map $H^k(X; R) \times H^l(Y; R) \xrightarrow{\times} H^{k+l}(X \times Y; R)$ given by

$$a \times b \equiv p_1^* a \smile p_2^* b$$

where p_i denotes the i-th projection map for each $i = 1, 2$. This indues a unique linear map

$$H^k(X; R) \otimes_R H^l(Y; R) \to H^{k+l}(X \times Y; R).$$

Note 41. The same definition works for $H^k(X, A; R) \times H^l(Y, B; R) \xrightarrow{\times} H^{k+l}(X \times Y, X \times B \cup A \times Y; R)$.

Note 42. We can view $H^*(X; R)$ as the *graded ring* $(\bigoplus_{k \geq 0} H^k(X; R), +, \smile)$.

Proposition 22. The cup product is a graded ring homomorphism.

Theorem 20. (Künneth (special case)) Suppose that X and Y are CW-complexes such that $H^n(Y; R)$ is a finitely generated free R-module for each n. Then $\times$ induces a ring isomorphism $H^*(X; R) \otimes_R H^*(Y; R) \to H^*(X \times Y; R)$, i.e.,

$$\bigoplus_{p+q=n} H^p(X; R) \otimes_R H^q(Y; R) \cong H^n(X \times Y; R)$$

for each n.

Remark 23. We could drop the assumption that X and Y are CW-complexes.

Definition. A *cohomology theory* h^* on CW-pairs is a sequence of contravariant functors from CW-pairs to graded abelian groups that satisfies the following properties.

1. If $f \simeq g$ as maps $X \to Y$, then $f^* = g^*$ as maps $h^*(Y) \to h^*(X)$.

2. $h^*(X, A) \cong h^*(X/A, \mathsf{pt})$.

3. For any CW-pair (X, A), there exists a LES

$$\cdots \longrightarrow h^n(X, A) \longrightarrow h^n(X) \longrightarrow h^n(A) \longrightarrow h^{n+1}(X, A) \longrightarrow \cdots.$$

4. $h^*(\bigvee_\alpha X_\alpha) \cong \prod_\alpha h^*(X_\alpha)$.

Lemma 37. Let $\mu : h_1^* \to h_2^*$ be a natural transformation of cohomology theories on CW-pairs. If $\mu(\mathsf{pt}, \emptyset) : h_1^*(\mathsf{pt}, \emptyset) \to h_2^*(\mathsf{pt}, \emptyset)$ is an isomorphism, then μ is an isomorphism for any CW-pair.

Proof. Due to the five lemma, it's enough to prove that for any CW-complex X, $\mu_X : h_1^*(X) \to h_2^*(X)$. Assuming that X is finite-dimensional, we do this by induction on the dimension of X. Since X^0 is a discrete set of points, our base case holds almost by assumption.

Suppose, inductively, that $\mu_{X^{n-1}}$ is an isomorphism. Since μ is a natural transformation, we get a commutative diagram with exact rows

$$
\begin{array}{ccccccccc}
h_1^k(X^n, X^{n-1}) & \longrightarrow & h_1^k(X^n) & \longrightarrow & h_1^k(X^{n-1}) & \longrightarrow & h_1^{k+1}(X^n, X^{n-1}) & \longrightarrow & \cdots \\
\downarrow{\mu} & & \downarrow{\mu} & & \downarrow{\mu(\cong)} & & \downarrow{\mu} & & \\
h_2^k(X^n, X^{n-1}) & \longrightarrow & h_2^k(X^n) & \longrightarrow & h_2^k(X^{n-1}) & \longrightarrow & h_2^{k+1}(X^n, X^{n-1}) & \longrightarrow & \cdots
\end{array}
$$

By the five lemma, we must need to show that $\mu : h_1^k(X^n, X^{n-1}) \to h_2^k(X^n, X^{n-1})$ is an isomorphism. We have another commutative diagram

$$
\begin{array}{ccc}
h_1^k(X^n, X^{n-1}) & \xrightarrow{\mu} & h_2^k(X^n, X^{n-1}) \\
\cong\downarrow & & \cong\downarrow \\
h_1^k(X^n/X^{n-1}) & \xrightarrow{\mu} & h_2^k(X^n/X^{n-1}) \\
\cong\downarrow & & \cong\downarrow \\
h_1^k(\bigvee_\alpha S^n) & \xrightarrow{\mu} & h_2^k(\bigvee_\alpha S^n) \\
\cong\downarrow & & \cong\downarrow \\
\prod_\alpha h_1^k(S^n) & \xrightarrow{\mu} & \prod_\alpha h_2^k(S^n)
\end{array}
$$

Thus, we want to show that bottommost μ is an isomorphism. Since S^{n-1} is an $(n-1)$-dimensional CW-complex and $D^n \simeq \mathsf{pt}$, applying the five lemma together with out IH to the LES for (D^n, S^{n-1}) proves that $h_1^k(S^n) \cong h_2^k(S^n)$.

The case where X is infinite-dimensional reduces to the case where it's finite-dimensional. We omit the details. $\square$

Proposition 23. Let Y be a CW-complex and $H^*(Y; R)$ be free over R. Consider the functors

$$h_1^*(X, A) \equiv H^*(X, A; R) \otimes_R H^*(Y; R)$$
$$h_2^*(X, A) \equiv H^*(X \times Y, A \times Y; R)$$

where X is a CW-complex. If $A = \emptyset$, then the map $\mu : h_1^*(X) \to h_2^*(X)$ given by $a \otimes b \mapsto a \times b$ defines a natural transformation $h_1^*(-) \to h_2^*(-)$.

Proof. (**Künneth**) It suffices to show that $\mu : h_1^*(X) \to h_2^*(X)$ is an isomorphism when $X = \mathsf{pt}$. But, in this case, μ is precisely the map $R \otimes_R H^n(Y; R) \to H^n(Y; R)$ given by $r \otimes y \mapsto ry$, which is a well-known isomorphism. $\qquad\square$

Example 41. $H^*(S^n) \otimes H^*(S^m) \cong H^*(S^n \times S^m)$.

4.2 Lecture 20

Theorem 21. (Künneth (special case)) Let (X, A) and (Y, B) be CW-pairs. If $H^k(Y, B; R)$ is a finitely generated free R-module for each k, then

$$H^*(X, A; R) \otimes_R H^*(X, B; R) \xrightarrow{\times} H^*(X \times Y, A \times Y \cup X \times B; R)$$

is a ring isomorphism.

Definition. Let (X, x_0) and (Y, y_0) be pointed spaces. The *smash product* $X \wedge Y$ is

$$(X \times Y)/(X \times \{y_0\} \cup \{x_0\} \times Y).$$

Remark 24. The smash product is a monoidal product in $\mathbf{Top}_*$.

Example 42.

1. $S^n \wedge S^m \cong S^{n+m}$.

   Proof. It suffices to show that if (X, x_0) and (Y, y_0) are compact manifolds, then $X \wedge Y \cong ((X \setminus \{x_0\}) \times (Y \setminus \{y_0\}))^*$ where $(-)^*$ denotes the one-point compactification. Let $Z := (X \setminus \{x_0\}) \times (Y \setminus \{y_0\})$. Note that Z is noncompact but locally compact.

   We see that $\psi := \pi \circ i : Z \to X \wedge Y$ is injective with $\operatorname{im} \psi = X \wedge Y \setminus \{(x_0, y_0)\}$. Let $U \subset Z$ be open. Then U is open in $X \times Y$. Since $\pi^{-1}(\pi(U)) = U$, it follows that $\pi(U)$ is open in $X \wedge Y$. Thus, ψ is an open map, so that ψ is a topological embedding. Since $X \wedge Y$ is compact, it follows that ψ is a Hausdorff compactification. $\qquad\square$

2. $S^1 \wedge X \cong (X \times I)/(X \times \{0\} \cup X \times \{1\} \cup \{x_0\} \times I)$, called the *reduced suspension ΣX of X*.

Example 43.

1. Let (X, x_0) and (Y, y_0) be pointed spaces with $H^*(Y, y_0)$ free and finitely generated over $\mathbb{Z}$. Then $H^*(X, x_0) \otimes H^*(Y, y_0) \cong H^*(X \times Y, X \times \{y_0\} \cup Y \times \{x_0\}) \cong H^*(X \wedge Y)$.

2. $\widetilde{H}(S^n) \times \widetilde{H}^m(S^m) \cong H^{n+m}(S^{n+m})$.

Note 43. Any polynomial ring is graded since $R[x] = \bigoplus_{n \in \mathbb{N}} Rx^n$.

Theorem 22. Let $X = \mathbb{CP}^n$ (resp. $\mathbb{RP}^n$) and $R = \mathbb{Z}$ (resp. $\mathbb{Z}/2$), then $H^*(X; R) \cong \left. R[\tilde{x}] \middle/ (\tilde{x}^{n+1}) \right.$ where $|\tilde{x}| = 2$ (resp. 1).

Proof. See Hatcher, Theorem 3.19 for a proof of the case where $X = \mathbb{RP}^n$. We will assume that $X = \mathbb{CP}^n$.

The inclusion $\mathbb{CP}^{n-1} \hookrightarrow \mathbb{CP}^n$ induces an isomorphism $H^k(\mathbb{CP}^{n-1}) \to H^k(\mathbb{CP}^n)$ when $k < 2n - 1$. Thus, it suffices to show that if $\omega \in H^{2i}(\mathbb{CP}^n)$ is a generator and $\omega' \in H^{2n-2i}(\mathbb{CP}^n)$ is a generator where $0 \le i \le n$ is even, then $\omega \smile \omega'$ generates $H^{2n}(\mathbb{CP}^n)$. Set $j = n - i$. Then $\mathbb{CP}^j = \{[z_0, \ldots, z_n] \mid z_0 = z_1 = \cdots = z_{i-1} = 0\}$, and $\mathbb{CP} \cap \mathbb{CP}^j = p := [0, \ldots, 0, \underbrace{1}_{i\text{-th spot}}, 0 \ldots, 0]$. Note that $\mathbb{CP}^i \cap U \cong \mathbb{C}^i$ and $\mathbb{CP}^j \cap U \cong \mathbb{C}^j$ where

$U = \{[x_0, \ldots, z_n] \mid z_i \neq 0\}$. Consider the commutative diagram

$$
\begin{array}{ccc}
H^{2i}(\mathbb{CP}^n) \times H^{2j}(\mathbb{CP}^n) & \xrightarrow{\ \smile\ } & H^{2n}(\mathbb{CP}^n) \\
\varphi_1 \big\uparrow & & \big\uparrow \cong \\
H^{2i}(\mathbb{CP}^n, \mathbb{CP}^n \setminus \mathbb{C}^j) \times H^{2j}(\mathbb{CP}^n, \mathbb{CP}^n \setminus \mathbb{C}^i) & \xrightarrow{\ \smile\ } & H^{2n}(\mathbb{CP}^n, \mathbb{CP}^n \setminus \{p\}) \\
\varphi_2 \big\downarrow & & \big\downarrow \cong \\
H^{2i}(\mathbb{C}^n, \mathbb{C}^n \setminus \mathbb{C}^j) \times H^{2j}(\mathbb{C}^n, \mathbb{C}^n \setminus \mathbb{C}^i) & \xrightarrow{\ \smile\ } & H^{2n}(\mathbb{C}^n, \mathbb{C}^n \setminus \{0\})
\end{array} \;,
$$

where the top right isomorphism comes from the five lemma applied to the LES's for $(\mathbb{CP}^n, \mathbb{CP}^n \setminus \{p\})$ and $(\mathbb{CP}^n, \mathbb{CP}^{n-1})$ and the bottom right isomorphism comes from excision.

Claim 3. Both φ_1 and φ_2 are isomorphisms.

Proof. We have a commutative diagram

$$
\begin{array}{ccccccc}
H^{2i}(\mathbb{CP}^n) & \xleftarrow{\cong} & H^{2i}(\mathbb{CP}^n, \mathbb{CP}^{i-1}) & \xleftarrow{\psi} & H^{2i}(\mathbb{CP}^n, \mathbb{CP}^n \setminus \mathbb{CP}^j) & \xrightarrow{\cong} & H^{2i}(\mathbb{C}^n, \mathbb{C}^n \setminus \mathbb{C}^j) \\
\cong \big\downarrow & & \cong \big\downarrow & & \big\downarrow & & \big\downarrow \\
H^{2i}(\mathbb{CP}^i) & \xleftarrow{\cong} & H^{2i}(\mathbb{CP}^i, \mathbb{CP}^{i-1}) & \xleftarrow{\gamma} & H^{2i}(\mathbb{CP}^i, \mathbb{CP}^i \setminus \{p\}) & \xrightarrow{\cong} & H^{2i}(\mathbb{C}^i, \mathbb{C}^i \setminus \{0\})
\end{array} \;,
$$

where ==the isomorphisms of the leftmost square come from cellular cohomology== and those from the rightmost square come from excision. It suffices to show that each map in this diagram is an isomorphism. Note that γ is an isomorphism because $\mathbb{CP}^i \setminus \{p\}$ deformation retracts onto $\mathbb{CP}^{i-1}$. Hence it suffices to observe that ψ is an isomorphism because $\mathbb{CP}^n \setminus \mathbb{CP}^j$ deformation retracts onto $\mathbb{CP}^{i-1}$. Indeed, $\mathbb{CP}^n \setminus \mathbb{CP}^j = \{[z_0, \ldots, z_n] \mid \exists s \in \{0, \ldots, i-1\}$ such that $z_s \neq 0\}$, so that the maps given by $f_t([z_0, \ldots, z_n]) = [z_0, \ldots, z_{i-1}, tz_i, \ldots, tz_n]$ $(1 \xrightarrow{t} 0)$ define a suitable deformation retraction. $\qquad\square$

Moreover, the map $H^{2i}(\mathbb{C}^n, \mathbb{C}^n \setminus \mathbb{C}^j) \times H^{2j}(\mathbb{C}^n, \mathbb{C}^n \setminus \mathbb{C}^i) \xrightarrow{\smile} H^{2n}(\mathbb{C}^n, \mathbb{C}^n \setminus \{0\})$ is equivalent to the map $H^{2i}(I^{2i}, \partial I^{2i}) \times H^{2j}(I^{2j}, \partial I^{2j}) \xrightarrow{\smile} H^{2n}(I^{2n}, \partial I^{2n})$, which maps any pair of generators to a generator by the Künneth theorem. By commutativity, it follows that $H^{2i}(\mathbb{CP}^n) \times H^{2j}(\mathbb{CP}^n) \xrightarrow{\smile} H^{2n}(\mathbb{CP}^n)$ also maps any pair of generators to a generator. $\qquad\square$

Corollary 27.

1. If $\mathbb{R}^n$ has a division algebra structure over $\mathbb{R}$, then $n = 2^l$ for some $l \in \mathbb{Z}_{\geq 0}$.

2. If $\mathbb{C}^n$ has a division algebra structure over $\mathbb{C}$, then $n = 1$.

Proof.

1. Suppose that $\mathbb{R}^n$ is a division algebra over $\mathbb{R}$. Then its bilinear product induces a continuous map $h : \mathbb{RP}^{n-1} \times \mathbb{RP}^{n-1} \to \mathbb{RP}^{n-1}$ such that $h \restriction_{\mathbb{RP}^{n-1} \times \{y\}}$ and $h \restriction_{\{x\} \times \mathbb{RP}^{n-1}}$ are homeomorphisms for any $x, y \in \mathbb{RP}^{n-1}$. The induced homomorphism $h^* : \mathbb{Z}_2[\tilde{x}]\big/(\tilde{x}^n) \to \mathbb{Z}_2[\tilde{x}_1, \tilde{x}_2]\big/(\tilde{x}_1^n, \tilde{x}_2^n)$ is determined by the value $\tilde{x} \mapsto k_1\tilde{x}_1 + k_2\tilde{x}_2$. Since h restricts to a homeomorphism on each copy of $\mathbb{RP}^{n-1}$, it follows that $k_1\tilde{x}_1$ and $k_2\tilde{x}_2$ are nonzero. Hence $k_1 = 1 = k_2$. But

$$
0 = \tilde{x}^n = (\tilde{x}_1 + \tilde{x}^2)^n = \sum_{k=1}^{n-1} \binom{n}{k} \tilde{x}_1^k \tilde{x}_2^{n-k}.
$$

   This implies that $\binom{n}{k} \equiv 0 \mod 2$ for each $1 \leq k \leq n - 1$.

   Exercise 7. Use elementary number theory to prove this happens only if n equals a power of 2.

2. By a similar argument, we deduce that $\binom{n}{k} = 0$ for each $1 \leq k \leq n - 1$. This implies that $n = 1$.

$\square$

Definition. Let X be any space.

1. We say that X *has category n* (written as $\operatorname{cat}(X) = n$) if X can be written as a union of n contractible open subsets but not $n-1$.

2. The *cup length* cup-length(X) *of X* is $\max\{c \in \mathbb{Z} \mid \exists x_1, \ldots, x_c \in H^*(X, \mathbb{Z})$ such that $|x_i| \geq 1$ and $x_i \cdots x_c \neq 0\}$.

Example 44. We know that $\mathbb{CP}^n = \bigcup_{i=0}^n U_i$ where $U_i := \{[z_0, \ldots, z_n] \mid z_i \neq 0\} \cong \mathbb{C}^n$. Is it possible to write $\mathbb{CP}^n$ as a union of n contractible subspaces?

Theorem 23. If X is a space, then $\operatorname{cat}(X) - 1 \geq$ cup-length(X).

Proof. Let $c := \operatorname{cat}(X)$. Then $X = \bigcup_{i=1}^c$ with each U_i open and contractible. By LES in cohomology, we get $H^j(X) \cong H^j(X, U_i)$ for any i and any $j \geq 1$. Suppose that $x_i \in H^{j_i}(X)$ for each $1 \leq i \leq c$ where $|x_i| \geq 1$. Then $x_1 \cdots x_c \in H^{j_1 + \cdots + j_c}(X, \bigcup_{i=1}^c U_i) = H^{j_1 + \cdots + j_c}(X, X) = 0$. Thus, $x_1 \cdots x_c = 0$. $\square$

Corollary 28. $\operatorname{cat}(\mathbb{CP}^n) \geq$ cup-length$(\mathbb{CP}^n) + 1 = n + 1$.

Definition. Let $k \geq l$. The *cap product* is the map $C_k(X; R) \times C^l(X; R) \xrightarrow{\frown} C_{k-l}(X; R)$ defined by

$$\sigma \frown \varphi = \varphi(\sigma \restriction_{[v_0, \ldots, v_l]}) \sigma \restriction_{[v_l, \ldots, v_k]} .$$

Lemma 38. $\partial(\sigma \frown \varphi) = (-1)^l(\partial \sigma \frown \varphi - \sigma \frown \delta\varphi)$.

Proof. We compute

$$\partial\sigma \frown \varphi = \sum_{i=0}^k (-1)^i \sigma \restriction_{[v_0, \ldots, \hat{v}_i, \ldots, v_k]} \frown \varphi$$

$$= \sum_{i=0}^l (-1)^i \varphi(\sigma \restriction_{[v_0, \ldots, \hat{v}_i, \ldots, v_{l+1}]}) \sigma \restriction_{[v_{l+1}, \ldots, v_k]}$$

$$+ \sum_{i=l+1}^k (-1)^i \varphi(\sigma \restriction_{[v_0, \ldots, v_l]}) \sigma \restriction_{[v_l, \ldots, \hat{v}_i, \ldots, v_k]}$$

$$\sigma \frown \delta\varphi = \delta\varphi(\sigma \restriction_{[v_0, \ldots, v_{l+1}]}) \sigma \restriction_{[v_{l+1}, \ldots, v_k]}$$

$$= \sum_{i=0}^{l+1} (-1)^i \varphi(\sigma \restriction_{[v_0, \ldots, \hat{v}_i, \ldots, v_{l+1}]}) \sigma \restriction_{[v_{l+1}, \ldots, v_k]}$$

$$\partial(\sigma \frown \varphi) = \partial(\varphi(\sigma \restriction_{[v_0, \ldots, v_l]}) \sigma \restriction_{[v_l, \ldots, v_k]})$$

$$= \sum_{i=l}^k (-1)^{i-l} \varphi(\sigma \restriction_{[v_0, \ldots, v_l]}) \sigma \restriction_{[v_l, \ldots, \hat{v}_i, \ldots, v_k]} .$$

It's easy to check that $(-1)^l \partial(\sigma \frown \varphi) = \partial\sigma \frown \varphi - \sigma \frown \delta\varphi$. $\square$

Corollary 29. The cap product induces a map $H_k(X; R) \times H^l(X; R) \xrightarrow{\frown} H_{k-l}(X; R)$.

Proof. If σ is a cycle and φ a cocycle, then clearly $\sigma \frown \varphi$ is a cycle. Also, if $\sigma = \partial d$ and $\delta\varphi = 0$, then $\sigma \frown \varphi = \partial d \frown \varphi = \pm\partial(d \frown \varphi)$. Hence the cap product of a boundary and cocycle is a boundary. Similarly, the cap product of a cycle and coboundary is a boundary. $\square$

Theorem 24. (Poincaré duality (PD)) Let X be a closed R-oriented n-manifold. Then the map $H^l(X; R) \to H_{n-l}(X; R)$ given by $\varphi \mapsto [X] \frown \varphi$ is an isomorphism for every l.

Remark 25. PD is a global consequence of one local condition (manifold-hood) and two global conditions (orientability and closedness).

4.3 Lecture 21

Note 44. We have the following relative forms of the cap product.

$$H_k(X, A \cup B) \times H^l(X, A) \xrightarrow{\frown} H_{k-l}(X, B)$$
$$H_k(X, A) \times H^l(X) \xrightarrow{\frown} H_{k-l}(X, A)$$
$$H_k(X, A) \times H^l(X, A) \xrightarrow{\frown} H_{k-l}(X)$$

Proposition 24. (Projection formula) Let $f : X \to Y$ be a map of spaces. Let $[\sigma] \in H_k(X)$ and $[\varphi] \in H^l(Y)$. Then

$$f_*([\sigma]) \frown [\varphi] = f_*([\sigma] \frown f^*([\varphi]))$$

in $H_{k-l}(Y)$.

Definition. Let X be a locally compact CW-complex. Let $C_c^i \equiv \{\varphi \in C^i(X; R) \mid \exists K_\varphi \subset X$ compact such that $\varphi(c) = 0$ for any $c \in C_i(X \setminus K_\varphi)\}$. This induces the *cohomology group with compact support* $H_c^i(X; R)$.

Note 45. The groups $C_c^i(X; R)$ consisting of cochains φ that are nonzero only on i-simplices contained in some compact set K_φ do not form a subcomplex of the singular cochain complex. Indeed, if $\varphi \in C^0(\mathbb{R})$ has $\varphi(x_0) = 1$ and $\varphi(x) = 0$ for any $x \neq x_0$, then $\delta\varphi(\sigma : \underbrace{y \rightsquigarrow x_0}_{y \neq x_0}) = \varphi(\sigma(1)) - \varphi(\sigma(0)) \neq 0$.

Example 45. Let X be a simplicial complex and let $C_c^i(X; G)$ denote the subgroup of compactly supported i-cochains. View $\mathbb{R}$ as a simplicial complex with vertices at the integer points. If $\varphi \in C_c^0$ satisfies $\delta\varphi = 0$, then φ must be constant since $\delta\varphi([n, n+1]) = \varphi(n+1) - \varphi(n)$ for every $n \in \mathbb{Z}$. In this case, φ must be identically zero since it is compactly supported. Thus, $H_c^0(\mathbb{R}, \mathbb{Z}) = 0$.

Define $\epsilon : C_c^1(\mathbb{R}; \mathbb{Z}) \to \mathbb{Z}$ by $\epsilon(\psi) = \sum_{n \in \mathbb{Z}} \psi([n, n+1])$, which makes sense since ψ is compactly supported. We have that

$$\epsilon(\delta\phi) = \sum_{n \in \mathbb{Z}} \delta\varphi([n, n+1]) = \sum_{n \in \mathbb{Z}} \varphi(n+1) - \varphi(n) = 0.$$

Thus, ϵ vanishes on any coboundary. Since $\boxed{\epsilon \neq 0}$, it follows that there are 1-cocycles that are not coboundaries, so that $H_c^1(\mathbb{R}; \mathbb{Z}) \neq 0$.

Exercise 8. Show that the induced map $\epsilon : H_c^1(\mathbb{R}; \mathbb{Z}) \to \mathbb{Z}$ is injective, i.e., if $\epsilon(\psi) = 0$, then $\psi = \delta\phi$ for some ϕ.

Definition.

1. Let i be a poset. We say that I is a *directed set* if for any $\alpha, \beta \in I$, there exists $\gamma \in I$ such that $\alpha, \beta \leq \gamma$.

   Let G_α be an abelian group for each $\alpha \in I$. Suppose that for any $\alpha \leq \beta$, there is some homomorphism $f_{\alpha\beta} : G_\alpha \to G_\beta$ such that

   - $f_{\alpha\alpha} = \mathbb{1}_{G_\alpha}$ for any $\alpha \in I$ and
   - $f_{\beta\gamma} \circ f_{\alpha\beta} = f_{\alpha\gamma}$ when $\alpha \leq \beta \leq \gamma$.

   Then $\{G_\alpha, f_{\alpha\beta}\}$ is called a *directed system* of groups.

2. Suppose that $\{G_\alpha, f_{\alpha\beta}\}$ is a directed system of groups. The *direct limit* group is

   $$\varinjlim G_\alpha \equiv \bigoplus_{\alpha \in I} G_\alpha \Big/ N$$

   where N is the subgroup generated by all elements of the form $a - f_{\alpha\beta}(a)$ with $a \in G_\alpha$.

   Equivalently, $\varinjlim G_\alpha$ has as its underlying set $\coprod_{\alpha \in I} G_\alpha / \sim$ where $x_\alpha \simeq x_\beta$ if there exists $\gamma \in I$ such that $\alpha, \beta \leq \gamma$ and $f_{\alpha\beta}(x_\alpha) = f_{\beta\gamma}(x_\beta)$. We equip this with the group structure

   $$[x_\alpha] + [x_\beta] = [f_{\alpha\gamma}(x_\alpha) + f_{\beta\gamma}(x_\beta)]$$

   where $\alpha, \beta \leq \gamma$. (This is well-defined because I is a poset by hypothesis.)

Aside. Let $\mathbf{Ab}^I$ denote the category of directed systems (viewed as functors $I \to \mathbf{Ab}$), so that a morphism in $\mathbf{Ab}^I$ is precisely a collection of homomorphisms $\{w_\alpha\} : \{G_\alpha, f_{\alpha\beta}\} \to \{H_\alpha, g_{\alpha\beta}\}$ such that the square

$$
\begin{array}{ccc}
G_\alpha & \xrightarrow{\ f_{\alpha\beta}\ } & G_\beta \\
{\scriptstyle w_\alpha}\big\downarrow & & \big\downarrow{\scriptstyle w_\beta} \\
H_\alpha & \xrightarrow[\ g_{\alpha\beta}\ ]{} & H_\beta
\end{array}
$$

commutes for any $\alpha \le \beta$. Let $a_\alpha : G_\alpha \to \varinjlim G_\alpha$ and $b_\alpha : H_\alpha \to \varinjlim H_\alpha$ denote the canonical maps. Then, by the universal property of colimits, the maps $b_\alpha \circ w_\alpha : G_\alpha \to \varinjlim H_\alpha$ induce a unique map $w : \varinjlim G_\alpha \to \varinjlim H_\alpha$ such that $w \circ a_\alpha = b_\alpha \circ w_\alpha$. The functor $\varinjlim : \mathbf{Ab}^I \to \mathbf{Ab}$ sends any morphism $\{w_\alpha\}$ to w.

Example 46. We have that $C_c^i(X; R) = \bigcup_{K \subset X} C^i(X, X \setminus K; R)$ with K compact in X. Note that the set K_X of compact sets in X is a directed set both under inclusion $\subset$ (for a directed system of homology groups) and under reverse inclusion $\supset$ (for a directed system of cohomology groups).

Proposition 25.

1. Let I be a directed set. Let $X = \bigcup_{\alpha \in I} X_\alpha$ such that any compact set in X is contained in some X_α. Then $\varinjlim H_i(X_\alpha; G) \cong H_i(X; G)$ for each i.

2. $\varinjlim_{K_X} H^i(X, X \setminus X_\alpha; R) \cong H_c^i(X; R)$.

Remark 26. (De Rham homology) Let X be a smooth n-manifold and consider its de Rham cochain complex $(\Omega^i(X), d)$. The *de Rham homology* $H_i(X)$ arises from the chain complex given by

$$
\Omega_i(X) \equiv \Omega^i(X)^\vee = \mathbb{R}[\{f : \Omega^i(X) \to \mathbb{R} \mid f \text{ continuous}\}]
$$

and $\partial \xi \equiv \xi d$. Note that $\Omega^i(X)^\vee$ is compactly supported.

Suppose that X is closed and oriented. The linear functional $\Omega^n(X) \to \mathbb{R}$ given by $\omega \mapsto \int_X \omega$ is called an *n-current*. Let $S \subset X$ be a closed k-submanifold. Then $\eta \mapsto \int_S d\eta \restriction_S = \int_{\partial S} \eta \restriction_S = 0$ defines a $(k-1)$-current $\Omega^{k-1}(X) \to \mathbb{R}$. We can view an element of $\Omega_i(X)$ as a distribution-valued form.

Further, we can take the topological dual of $(\Omega_c^*(X), d)$, but it won't be compactly supported. This dual $\Omega_*^{\mathrm{BM}}(X)$ induces the so-called *Borel-Moore homology of X*. Another version of PD states that if X is an oriented n-manifold, then

$$
H_{\mathrm{dR},c}^k(X) \cong H_{n-k}^{\mathrm{dR}}(X)
$$
$$
H_{\mathrm{dR}}^k(X) \cong H_{n-k}^{\mathrm{BM}}(X).
$$

Note 46. Let X be an n-manifold with orientation $x \mapsto \alpha_x$. Let $K \subset L \subset X$ be a chain of compact subsets. We have a commutative diagram

$$
\begin{array}{ccc}
H_n(X, X \setminus L; R) \times H^k(X, X \setminus L; R) & \xrightarrow{\ \frown\ } & H_{n-k}(X; R) \\
{\scriptstyle i_*}\big(\quad\big){\scriptstyle i^*} & & \\
H_n(X, X \setminus K; R) \times H^k(X, X \setminus K; R) & &
\end{array}
\quad .
$$

There exist unique $\mu_K \in H_n(X, X \setminus K)$ and $\mu_L \in H_n(X, X \setminus L)$ such that $\mu_K(x) = \alpha_x$ and $\mu_L(y) = \alpha_y$ for each $x \in K$ and each $y \in L$. By uniqueness, $i_*(\mu_L) = \mu_K$. By naturality of $\frown$,

$$
\mu_K \frown x = i_*(\mu_L) \frown x = \mu_L \frown i^*(x)
$$

for any $x \in H^k(X, X \setminus K)$. Therefore, the direct limit (over K_X) of the maps $g_K : H^k(X, X \setminus K) \to H_{n-k}(X)$ given by $x \mapsto \mu_K \frown x$ induces the *duality homomorphism*

$$
D_X : H_c^k(X) \to H_{n-k}(X).
$$

4.4 Lecture 22

Remark 27. Any proper map of locally compact CW-complexes $f : X \to Y$ induces a homomorphism $f^* : H_c^*(Y; R) \to H_c^*(X; R)$. It also induces a map $C_c(Y) \to C_c(X)$ where $C_c(-)$ where $C_c(\cdot)$ denotes the space of compactly supported maps $\cdot \to \mathbb{R}$.

But we also have a *wrong way functor* or an *umkehr map* in that the inclusion $i : U \to V$ of open sets in X induces a homomorphism $i_! : H_c^k(U; R) \to H_c^k(V; R)$. It also induces a map $C_c(U) \to C_c(V)$ since every CW-complex is paracompact and thus always admits subordinate partitions of unity.

Note 47. Let $U \subset V$ be an inclusion of open sets in X. By applying excision twice, we see that $\varinjlim_{K_U} H^k(X, X \setminus K) = \varinjlim_{K_V} H^k(X, X \setminus K)$.

Proposition 26. Let X be an R-oriented n-manifold. Let U and V be open in X with $X = U \cup V$. Then there exists a commutative diagram up to sign

$$
\begin{array}{ccccccccc}
\cdots & \longrightarrow & H_c^k(U \cap V) & \longrightarrow & H_c^k(U) \oplus H_c^k(V) & \longrightarrow & H_c^k(X) & \longrightarrow & H_c^{k+1}(U \cap V) & \longrightarrow & \cdots \\
& & \downarrow{\scriptstyle D_{U \cap V}} & & \downarrow{\scriptstyle D_U \oplus - D_V} & & \downarrow{\scriptstyle D_X} & & \downarrow{\scriptstyle D_{U \cap V}} & & \\
\cdots & \longrightarrow & H_{n-k}(U \cap V) & \longrightarrow & H_{n-k}(U) \oplus H_{n-k}(V) & \longrightarrow & H_{n-k}(X) & \longrightarrow & H_{n-k-1}(U \cap V) & \longrightarrow & \cdots
\end{array}
$$

Theorem 25. Let X be an R-oriented n-manifold. Then $D_X : H_c^k(X) \to H_{n-k}(X)$ is an isomorphism for each i.

Proof.

Step 1: If $X = U \cup V$ with U and V open and D_U, D_V, and $D_{U \cap V}$ are isomorphisms, then D_X is an isomorphism.

   Proof. Apply the five lemma to the diagram of our last proposition. $\qquad\square$

Step 2: Suppose that X equals the union of a sequence of open sets $U_1 \subset U_2 \subset \cdots$. If each $D_{U_i} : H_c^k(U_i) \to H_{n-k}(U_i)$ is an isomorphism, then so is D_X.

   Proof. By excision, we have that

   $$
   H_c^k(U_i) \cong \varinjlim_{K_{U_i}} H^k(U_i, U_i \setminus K) \cong \varinjlim_{K_{U_i}} H^j(X, X \setminus K)
   $$

   for each i. From this, we see that there are natural maps $H_c^k(U_i) \to H_c^k(U_{i+1})$. Hence we can take $\varinjlim H_c^k(U_i) \cong H_c^k(X)$. Also, Proposition 25(1) implies that $\varinjlim H_{n-k}(U_i) \cong H_{n-k}(X)$, so that $D_X = \varinjlim D_{U_i}$. The direct limit preserves any isomorphism since it is a functor. Therefore, D_X is an isomorphism. $\qquad\square$

   Note 48. Our proof of Step 2 works so long as the directed set is totally ordered.

Step 3: If $X = \mathbb{R}^n$, then D_X is an isomorphism.

   Proof. Note that $\mathbb{R}^n \cong \operatorname{Int} \Delta^n$. Therefore, $H_c^k(\mathbb{R}^n) \cong H^k(\Delta^n, \partial \Delta^n)$. We can thus can view the map D_X as the map

   $$
   \tau : H^k(\Delta^n, \partial \Delta^n) \to H_{n-k}(\Delta^n)
   $$

   given by $x \mapsto [\Delta^n] \frown x$ where Δ^n denotes the identity map $\Delta^n \to \Delta^n$, which represents a generator of $H_n(\Delta^n, \partial \Delta^n)$. If $k \neq n$, then τ is the automorphism of the trivial group. Suppose that $k = n$. Note that $H^n(\Delta^n, \partial \Delta^n) \cong \operatorname{Hom}(H_n(\Delta^n, \partial \Delta^n), R)$ by the universal coefficient theorem, where any generator of $H^n(\Delta^n, \partial \Delta^n)$ is represented by a cocycle φ such that $\varphi([\Delta^n]) = 1$. But then

   $$
   \tau(\varphi) = [\Delta^n] \frown \varphi = \varphi(\sigma \restriction_{[v_0, \ldots, v_n]}) \operatorname{id}_{v_n} = \operatorname{id}_{v_n},
   $$

   which represents a generator of $H_0(\Delta^n)$. Thus, τ is an isomorphism. $\qquad\square$

Step 4: If U is any open set in $\mathbb{R}^n$, then D_U is an isomorphism.

Proof. Since $\mathbb{R}^n$ is second countable, we can write $U = \bigcup_{i \in \mathbb{N}} U_i$ where each $U_i \subset \mathbb{R}^n$ is an open ball. Let $V_i = \bigcup_{j \leq i} U_j$, so that $V_1 \subset V_2 \subset \cdots$.

We claim that each each D_{V_i} is an isomorphism. To do this, we prove the slightly more general claim that if Z_s is any finite union $\bigcup_{k=1}^s B_k$ of open balls in $\mathbb{R}^n$, then D_{Z_s} is an isomorphism. The base case follows automatically from Step 3. The inductive step holds because both Z_s and $Z_s \cap B_{s+1}$ equal the union of s open balls, in which case Step 1 implies that $D_{Z_s \cup B_{s+1}} = D_{Z_{s+1}}$ is an isomorphism.

Since $\bigcup_{i=1}^\infty V_i = U$ and each D_{V_i} is an isomorphism, it follows from Step 2 that D_U is an isomorphism. $\square$

Step 5: If X is any finite or countable union of open sets each of which is homeomorphic to $\mathbb{R}^n$, then D_X is an isomorphism.

Proof. Use a nearly identical proof to that of Step 4. $\square$

Step 6: If X is any noncompact manifold, then D_X is an isomorphism.

Proof. Let $\mathcal{U}$ denote the set of open $U \subset X$ such that D_U is an isomorphism. Order $\mathcal{U}$ by inclusion. Any chain in $\mathcal{U}$ has an upper bound due to Step 2. By Zorn's lemma, it follows that $\mathcal{U}$ has some maximal element U_0. If there exists $x \in X \setminus U_0$, then find a neighborhood U_x of x that is homeomorphic to $\mathbb{R}^n$. In this case, D_{U_x} is an isomorphism due to Step 3 and $D_{U_x \cap U_0}$ is an isomorphism due to Step 4, so that $D_{U_x \cup U_0}$ is an isomorphism due to Step 1. But this is impossible since U_0 is maximal. Thus, $U_0 = X$. $\square$

$\square$

Corollary 30. If X is a closed R-oriented manifold of odd dimension n, then $\chi(X) = 0$.

Proof. We have that

$$\chi(X) = \sum_i (-1)^i \operatorname{rank} H_i(X)$$
$$= \sum_i (-1)^i \operatorname{rank} H^{n-i}(X)$$
$$= \sum_i (-1)^i \operatorname{rank} H_{n-i}(X) = 0.$$

$\square$

Exercise 9. Let X be a closed manifold. Use the universal coefficient theorem to show that the value $\sum_i (-1)^i \operatorname{rank} H_i(X; \mathbb{Z})$ remains the same when $\mathbb{Z}$ is replaced by any R.

Corollary 31. Since any manifold X is $\mathbb{Z}/2$-oriented, $\chi(X) = 0$ whenever X is closed and $\dim X$ is odd.

Remark 28. Take any finite-dimensional simplicial complex X and embed X into some $\mathbb{R}^N$. Take a tubular neighborhood U of X in $\mathbb{R}^N$. Then U is a non-compact manifold such that $U \simeq X$. This suggests that the (co)homology of compact manifolds is much richer than that of non-compact ones.

Example 47. Let X be a closed R-oriented 4-manifold that is simply connected. By PD, we quickly get

$$H^k(X) \cong \begin{cases} \mathbb{Z} & k = 0, 4 \\ \pi_1(X)_{ab} = 0 & k = 3 \end{cases}.$$

By the universal coefficient theorem, it follows that $H^1(X) = 0$. Finally, the same theorem shows that $H_2(X) \cong H^2(X) \cong \operatorname{Hom}(H_2(X), \mathbb{Z})$, which is a free abelian group since $H_2(X)$ is finitely generated.

Proposition 27. If X and Y are oriented n-manifolds, then

$$H^k(X \# Y) \cong \begin{cases} H^k(X) \oplus H^k(Y) & 0 < k < n \\ \mathbb{Z} & k = 0, n \end{cases}.$$

Definition. Let X be a closed R-orientable n-manifold. Consider the bilinear form

$$B : H^k(X; R) \times H^{n-k}(X; R) \to R$$

given by $(f, g) \mapsto (f \smile g)[X]$. We say that B is *nondegenerate* or *nonsingular* if the induced maps $H^k(X; R) \to \operatorname{Hom}_R(H^{n-k}(X; R), R)$ and $H^{n-k}(X; R) \to \operatorname{Hom}_R(H^k(X; R), R)$ are both isomorphisms.

Lemma 39. If $\varphi \in C_k(X; R)$, $\psi \in C^l(X; R)$, and $\alpha \in C_{k+l}(X; R)$, then $\psi(\alpha \frown \varphi) = (\varphi \smile \psi)(\alpha)$.

Proof. We compute

$$\begin{aligned} \psi(\alpha \frown \varphi) &= \psi(\varphi(\sigma \restriction_{[v_0, \ldots, v_k]})\sigma \restriction_{[v_k, \ldots, v_{k+l}]}) \\ &= \varphi(\sigma \restriction_{[v_0, \ldots, v_k]})\psi(\sigma \restriction_{[v_k, \ldots, v_{k+l}]}) = (\varphi \smile \psi)(\alpha). \end{aligned}$$

$\square$

Theorem 26. Our bilinear form B is nondegenerate modulo torsion.

Proof. Consider the composition

$$H^{n-k}(X; R) \xrightarrow{h} \operatorname{Hom}_R\left(H_{n-k}(X; R), R\right) \xrightarrow{D^*} \operatorname{Hom}_R\left(H^k(X; R), R\right).$$

The map h is obtained from the universal coefficient theorem and is an isomorphism modulo torsion. Moreover, D^*h maps each $f \in H^{n-k}(X; R)$ to the homomorphism given by $g \mapsto f([X] \frown g) = (f \smile g)[X]$. Since D is an isomorphism, it follows that B is nondegenerate in its second factor. It is also nondegenerate in its first factor because of the commutativity of the cup product. $\square$

Remark 29. For any $4k$-manifold X, both rank H^{2k} and the signature of $B : H^{2k} \times H^{2k} \to H^{4k}$ are ==topological== invariants over $\mathbb{R}$ where the *signature of B* is $\#(\text{positive eigenvalues of } B) - \#(\text{negative eigenvalues of } B)$. The former, however, is the only such invariant over $\mathbb{C}$.

Theorem 27. (Friedman) Any oriented closed simply connected $4k$-manifold is classified up to homeomorphism by the signature of B (along with, sometimes, a $\mathbb{Z}/2$-valued invariant).

4.5   Lecture 23

Definition. Let $\mathbb{H}^n := \{(x^1, \ldots, x^n) \in \mathbb{R}^n : x_n \geq 0\}$. An *$n$-dimensional manifold with boundary M* is a Hausdorff space such that for any $p \in M$, there exist a neighborhood U of p and a homeomorphism $\varphi : U \to \mathbb{H}^n$. Any point $p \in M$ is called a *boundary point* if it belongs to $\varphi^{-1}(\{x_n = 0\})$.

Proposition 28. For any compact manifold with boundary M, there exists a *collar neighborhood* of ∂M, i.e., an open $U \supset \partial M$ such that $U \cong \partial M \times [0, 1)$.

Definition. A manifold with boundary is *R-oriented* if $M \setminus \partial M = \operatorname{Int} M$ is R-oriented.

Proposition 29. Let M be a compact n-manifold with boundary. Find $\partial M \times [0, 1)$ a collar neighborhood of ∂M. Then

$$H_n(M, \partial M; R) \cong H_n(M \setminus \partial M, \partial M \times (0, \epsilon)).$$

Corollary 32. If M is R-oriented, then we obtain a relative fundamental class $[M] \in H_n(M, \partial M; R)$, which restricts to a given orientation at every point in $M \setminus \partial M$.

Theorem 28. (Lefschetz duality) Let M^n be an R-oriented compact manifold with boundary. Then the map $D_M : H^k(M, \partial M; R) \to H_{n-k}(M; R)$ given by $D\varphi = [M] \frown \varphi$ is an isomorphism.

Proof. We will suppress our notation for the coefficient ring R. Let C denote the directed set of compact sets K contained in a complement of collar neighbohood of ∂M. Observe that

$$H_c^k(\operatorname{Int} M) \cong \varinjlim_{K \subseteq \operatorname{Int} M} H^k(\operatorname{Int} M, \operatorname{Int} M \setminus K)$$
$$\cong \varinjlim_{C} H^k(M, M \setminus K) \cong \varinjlim_{\epsilon\text{-collars } U} H^k(M, U)$$
$$\cong H^k(M, \partial M).$$

By PD, it follows that

$$H^k(M, \partial M) \cong H_c^k(\operatorname{Int} M) \cong H_{n-k}(\operatorname{Int} M) \cong H_{n-k}(M).$$

$\square$

Definition.

1. A *double (cochain) complex* is a commutative diagram

$$
\begin{array}{ccccccc}
\vdots & & \vdots & & \vdots & & \\
{\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
A^{0,2} & \xrightarrow{\ \delta\ } & A^{1,2} & \xrightarrow{\ \delta\ } & A^{2,2} & \xrightarrow{\ \delta\ } & \cdots \\
{\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
A^{0,1} & \xrightarrow{\ \delta\ } & A^{1,1} & \xrightarrow{\ \delta\ } & A^{2,1} & \xrightarrow{\ \delta\ } & \cdots \\
{\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
A^{0,0} & \xrightarrow{\ \delta\ } & A^{1,0} & \xrightarrow{\ \delta\ } & A^{2,0} & \xrightarrow{\ \delta\ } & \cdots
\end{array}
$$

   in **Ab** such that $d^2 = 0 = \delta^2$ and $d\delta + \delta d = 0$.

2. If $(A^{\bullet,\bullet}, d^{\bullet}, \delta^{\bullet})$ denotes a double complex, then the *total complex* $\mathrm{Tot}(A)$ *of* A is the single complex with $\mathrm{Tot}(A)^n \equiv \bigoplus_{p+q=n} A^{p,q}$ and $d_{\mathrm{Tot}(A)}\restriction_{A^{p,q}} \equiv \delta + (-1)^p d$.

3. If $(A^{\bullet,\bullet}, d^{\bullet}, \delta^{\bullet})$ denotes a double complex, then define the *cohomology of* A as

$$
H^*(A, d, \delta) = H^*(\mathrm{Tot}(A), d_{\mathrm{Tot}(A)}).
$$

Lemma 40. Suppose that

$$
\begin{array}{ccccccccc}
\vdots & & \vdots & & \vdots & & \vdots & & \\
\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
0 & \longrightarrow & A^2 & \xrightarrow{\ \epsilon\ } & A^{0,2} & \xrightarrow{\ \delta\ } & A^{1,2} & \xrightarrow{\ \delta\ } & \cdots \\
\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
0 & \longrightarrow & A^1 & \xrightarrow{\ \epsilon\ } & A^{0,1} & \xrightarrow{\ \delta\ } & A^{1,1} & \xrightarrow{\ \delta\ } & \cdots \\
\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
0 & \longrightarrow & A^0 & \xrightarrow{\ \epsilon\ } & A^{0,0} & \xrightarrow{\ \delta\ } & A^{1,0} & \xrightarrow{\ \delta\ } & \cdots
\end{array}
$$

and

$$
\begin{array}{ccccccc}
\vdots & & \vdots & & \vdots & & \\
{\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
A^{0,1} & \xrightarrow{\ \delta\ } & A^{1,1} & \xrightarrow{\ \delta\ } & A^{2,1} & \xrightarrow{\ \delta\ } & \cdots \\
{\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & {\scriptstyle d}\uparrow & & \\
A^{0,0} & \xrightarrow{\ \delta\ } & A^{1,0} & \xrightarrow{\ \delta\ } & A^{2,0} & \xrightarrow{\ \delta\ } & \cdots \\
{\scriptstyle \epsilon}\uparrow & & {\scriptstyle \epsilon}\uparrow & & {\scriptstyle \epsilon}\uparrow & & \\
A^0 & \xrightarrow{\ \delta\ } & A^1 & \xrightarrow{\ \delta\ } & A^2 & \xrightarrow{\ \delta\ } & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
0 & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & \cdots
\end{array}
$$

are augmented double complexes with exact rows and exact columns, respectively. Then there exists a cochain map $(A^{\bullet}, d) \to (\mathrm{Tot}(A^{\bullet,\bullet}), d_{\mathrm{Tot}})$ that induces an isomorphism $H^*(A^{\bullet}, d) \to H^*(A^{\bullet,\bullet}, d, \delta)$.

Proof. We just consider the case where the rows of $A^{\bullet,\bullet}$ are augmented. Note that $d_{\mathrm{Tot}}\epsilon = (\delta + d)\epsilon = d\epsilon = \epsilon d$. Hence $\epsilon^{\bullet}$ is a cochain map, thereby inducing a map $\epsilon^* : H^*(A^{\bullet}, d) \to H^*(A^{\bullet,\bullet}, d, \delta)$. We want to prove that

ϵ^* is bijective.

Let $[c] \in H^*(A^{\bullet,\bullet}, d, \delta)$, so that $D(c) = 0$. Write $c = (c_0, \dots, c_n)$. Since each row is exact by hypothesis, there is some s such that $\delta(s) = c_0$. We have that $c - d_{\text{Tot}}(s) = (0, c'_1, \dots, c'_n)$ for some c'_i. By repeating this procedure enough times, we get $[c] = [(0, \dots, 0, v_n)]$ for some v_n. Note that $\delta(v_n) = 0 = d(v_n)$. Hence there is some z such that $\epsilon(z) = v_n$. But $\epsilon(d(z)) = d(v_n) = 0$, and ϵ is injective. Thus, $d(z) = 0$. This proves that

$$\epsilon([z]) = [(0, \dots, 0, \epsilon(z))] = [(0, \dots, 0, v_n)] = [c],$$

so that ϵ^* is surjective.

Suppose that $\epsilon^*([v]) = 0$, so that $\epsilon(v) = d_{\text{Tot}}(p) = \delta \pm d(p)$ for some p. Note that $\delta(p) = 0$. Thus, as before, we get $[p] = [(0, \dots, 0, p_n)]$ for some p_n, so that $\epsilon(v) = D(0, \dots, 0, p_n)$. This implies that $\delta(p_n) = 0$. Since each row is exact, there is some y such that $\epsilon(y) = p_n$. Then

$$
\begin{aligned}
\epsilon(v) &= \delta(p_n) + d(p_n) \\
&= 0 + d(\epsilon(y)) \\
&= \epsilon(d(y)).
\end{aligned}
$$

Since ϵ is injective, it follows that v is a coboundary, i.e., $[v] = 0$. Therefore, ϵ^* is injective. $\qquad\square$

Definition. Let M be a smooth n-manifold and Λ be a countable poset. An open cover $\{U_\alpha\}_{\alpha \in \Lambda}$ of X is a *good cover* if for any chain $\alpha_0 \leq \cdots \leq \alpha_k$ in Λ, we have that

$$U_{\alpha_0 \dots \alpha_k} := U_{\alpha_0} \cap \cdots \cap U_{\alpha_k}$$

is either empty or diffeomorphic to $\mathbb{R}^n$.

Note 49. It is well known that every paracompact smooth n-manifold M admits a Riemannian metric. Further, one can show that M can be covered by finitely many geodesically convex open sets. Thus, M has a finite good cover.

Definition. Let M be a paracompact smooth n-manifold, so that it has some finite good cover $\mathcal{U} := \{U_{\alpha_i}\}$. The *Čech–de-Rham complex* $\check{C}^\bullet(\mathcal{U}; \Omega^\bullet)$ of $\mathcal{U}$ is the double complex

where

$$(\delta\omega)_{\alpha_0 \dots \alpha_{p+1}} \equiv \sum_{i=0}^{p+1} (-1)^i \omega_{\alpha_0 \dots \hat{\alpha}_i \dots \alpha_{p+1}} \lceil_{U_{\alpha_0 \dots \alpha_{p+1}}} .$$

Example 48. Let $\omega \in \prod_{\alpha_0} \Omega^q(U_{\alpha_0})$. Then $(\delta\omega)_{\alpha_0\alpha_1} = \omega_{\alpha_1} \lceil_{U_{\alpha_0\alpha_1}} -\omega_{\alpha_0} \lceil_{U_{\alpha_0\alpha_1}}$. From this, we compute

$$
\begin{aligned}
(\delta\delta\omega)_{\alpha_0\alpha_1\alpha_2} &= (\delta\omega)_{\alpha_1\alpha_2} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} -(\delta\omega)_{\alpha_0\alpha_2} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} +(\delta\omega)_{\alpha_0\alpha_1} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} \\
&= \omega_{\alpha_2} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} -\omega_{\alpha_1} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} -\omega_{\alpha_2} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} \\
&\quad + \omega_{\alpha_0} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} +\omega_{\alpha_1} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} -\omega_{\alpha_0} \lceil_{U_{\alpha_0\alpha_1\alpha_2}} \\
&= 0.
\end{aligned}
$$

If X is a space, then let $C_{lc}(X, \mathbb{R})$ denote the additive group of locally constant functions $X \to \mathbb{R}$. Now, let $\check{C}^\bullet(\mathcal{U}; \Omega^\bullet)$ denote the augmented Čech-de-Rham complex

$$
\begin{array}{ccccccccc}
\vdots & & \vdots & & \vdots & & \vdots & & \\
\big\uparrow & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} \\
0 \longrightarrow & \Omega^2(M) & \xrightarrow{\;\epsilon\;} & \prod_{\alpha_0} \Omega^2(U_{\alpha_0}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1} \Omega^2(U_{\alpha_0\alpha_1}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1\alpha_2} \Omega^2(U_{\alpha_0\alpha_1\alpha_2}) & \xrightarrow{\;\delta\;} \cdots \\
\big\uparrow & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} \\
0 \longrightarrow & \Omega^1(M) & \xrightarrow{\;\epsilon\;} & \prod_{\alpha_0} \Omega^1(U_{\alpha_0}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1} \Omega^1(U_{\alpha_0\alpha_1}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1\alpha_2} \Omega^1(U_{\alpha_0\alpha_1\alpha_2}) & \xrightarrow{\;\delta\;} \cdots \\
\big\uparrow & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} & & \big\uparrow{\scriptstyle d} \\
0 \longrightarrow & \Omega^0(M) & \xrightarrow{\;\epsilon\;} & \prod_{\alpha_0} \Omega^0(U_{\alpha_0}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1} \Omega^0(U_{\alpha_0\alpha_1}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1\alpha_2} \Omega^0(U_{\alpha_0\alpha_1\alpha_2}) & \xrightarrow{\;\delta\;} \cdots \\
& & & \big\uparrow & & \big\uparrow & & \big\uparrow & \\
& & & \prod_{\alpha_0} C_{lc}(U_{\alpha_0}, \mathbb{R}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1} C_{lc}(U_{\alpha_0\alpha_1}, \mathbb{R}) & \xrightarrow{\;\delta\;} & \prod_{\alpha_0\alpha_1\alpha_2} C_{lc}(U_{\alpha_0\alpha_1\alpha_2}, \mathbb{R}) & \xrightarrow{\;\delta\;} \cdots \\
& & & \big\uparrow & & \big\uparrow & & \big\uparrow & \\
& & & 0 & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow \cdots
\end{array}
$$

where $(\epsilon\omega)_{\alpha_0} \equiv \omega \restriction_{U_{\alpha_0}}$. The cohomology of the bottom row of $\check{C}^\bullet(\mathcal{U}; \Omega^\bullet)$ is known as the *Čech cohomology of $\mathcal{U}$ with coefficients in $\mathbb{R}$* and is denoted by $\check{H}^*(\mathcal{U}; \mathbb{R})$.

Lemma 41. The rows of $\check{C}^\bullet(\mathcal{U}; \Omega^\bullet)$ are exact.

Proof. It is clear that $\delta\epsilon = 0$. Since $\delta^2 = 0$, it just remains to check that $\ker \delta \subset \operatorname{im} \delta$ and $\ker \delta \subset \operatorname{im} \epsilon$. Let $\omega \in \prod_{\alpha_0 \ldots \alpha_p} \Omega^q(U_{\alpha_0 \ldots \alpha_p})$ such that $\omega \in \ker \delta$. Then $(\delta\omega)_{\alpha\alpha_0 \ldots \alpha_p} = \omega_{\alpha_0 \ldots \alpha_p} + \sum_{i=0}^p (-1)^{i+1} \omega_{\alpha\alpha_0 \ldots \hat{\alpha}_i \ldots \alpha_p} = 0$, so that

$$
\omega_{\alpha_0 \ldots \alpha_p} = \sum_{i=0}^p (-1)^i \omega_{\alpha\alpha_0 \ldots \hat{\alpha}_i \ldots \alpha_p}.
$$

Now, choose a partition of unity $\{\lambda_\alpha\}$ subordinate to $\mathcal{U}$. Define $s\omega \in \prod_{\alpha_0 \ldots \alpha_{p-1}} \Omega^q(U_{\alpha_0 \ldots \alpha_{p-1}})$ by

$$
(s\omega)_{\alpha_0 \ldots \alpha_{p-1}} = \sum_\alpha \lambda_\alpha \omega_{\alpha\alpha_0 \ldots \alpha_{p-1}}.
$$

We have that

$$
\begin{aligned}
(\delta s\omega)_{\alpha_0 \ldots \alpha_p} &= \sum_{i=0}^p (-1)^i (s\omega)_{\alpha_0 \ldots \hat{\alpha}_i \ldots \alpha_p} \\
&= \sum_{i=0}^p \sum_\alpha (-1)^i \lambda_\alpha \omega_{\alpha\alpha_0 \ldots \hat{\alpha}_i \ldots \alpha_p} \\
&= \sum_\alpha \sum_{i=0}^p (-1)^i \lambda_\alpha \omega_{\alpha\alpha_0 \ldots \hat{\alpha}_i \ldots \alpha_p} \\
&= \sum_\alpha \lambda_\alpha \omega_{\alpha_0 \ldots \alpha_p} \\
&= \omega_{\alpha_0 \ldots \alpha_p}.
\end{aligned}
$$

This shows that $\delta s\omega = \omega$, so that $\omega \in \operatorname{im} \delta$, as desired.

The fact that $\ker \delta \subset \operatorname{im} \epsilon$ is seen by gluing differential forms on U_α together to get a form on M. $\qquad\square$

Proposition 30. Let V be a smooth vector field and ω, η be differential forms. Let $\mathcal{L}$ denote the Lie derivative.

1. $i_V(\omega \wedge \eta) = i_V(\omega) + \eta + (-1)^{|\omega|}\omega \wedge i_V\eta$.

2. **(Cartan's magic formula)** $\mathcal{L}_V\omega = i_V d(\omega) + d(i_V\omega)$.

Lemma 42. (Poincaré) Let $F : M \times I \to N$ be a smooth map where N is a smooth manifold. Let i_- denote interior multiplication. For any $t \in I$, define $j_t : M \to M \times I$ by $j_t(p) = (p, t)$. For any $q \in \mathbb{N}$, define $\sigma : \Omega^q(N) \to \Omega^{q-1}(M)$ by

$$(\sigma\omega)_p = \left(x \mapsto \int_0^1 j_t^* i_{\frac{\partial}{\partial t}}(F^*\omega)(x)dt\right)$$

where $x \in \bigwedge^{q-1}(T_p^*M)$. Then $(d\sigma + \sigma d)\omega = F_1^*\omega - F_0^*\omega$. That is, σ is a cochain homotopy $F_0^* \Rightarrow F_1^*$.

Proof. Using our last proposition, we compute

$$d\sigma\omega(x) + \sigma d\omega(x) = \int_0^1 dj_t^* i_{\frac{\partial}{\partial t}}(F^*\omega)(x)dt + \int_0^1 j_t^* i_{\frac{\partial}{\partial t}}(F^* d\omega)(x)dt$$

$$= \int_0^1 j_t^* di_{\frac{\partial}{\partial t}}(F^*\omega)(x)dt + \int_0^1 j_t^* i_{\frac{\partial}{\partial t}}(dF^*\omega)(x)dt$$

$$= \int_0^1 j_t^* \mathcal{L}_{\frac{\partial}{\partial t}} F^*\omega(x)dt.$$

Note that the flow of $(0, \frac{\partial}{\partial t})$ is given by $\theta_t(p, s) = (p, t + s)$. Hence $F \circ \underbrace{\theta_t \circ j_0}_{j_t} = F_t$. It follows that

$$j_t^* \mathcal{L}_{\frac{\partial}{\partial t}} F^*\omega = j_0^* \theta_t^* \mathcal{L}_{\frac{\partial}{\partial t}} F^*\omega$$

$$= j_0^* \frac{d}{dt} \theta_t^* F^*\omega$$

$$= \frac{d}{dt} j_0^* \theta_t^* F^*\omega$$

$$= \frac{d}{dt} F_t^*\omega.$$

As a result, we can use Stokes' theorem to get

$$d\sigma\omega(x) + \sigma d\omega(x) = \int_0^1 j_t^* \mathcal{L}_{\frac{\partial}{\partial t}} F^*\omega(x)dt$$

$$= \int_0^1 \frac{d}{dt} F_t^*\omega(x)dt$$

$$= \int_0^1 dF_t^*\omega(x)$$

$$= F_1^*\omega(x) - F_0^*\omega(x).$$

$\square$

Corollary 33. If $U \cong \mathbb{R}^n$, then the sequence

$$\mathbb{R} \to \Omega^0(U) \to \Omega^1(U) \to \Omega^2(U) \to \cdots$$

is exact. Therefore, the columns of $\check{C}^\bullet(\mathcal{U}; \Omega^\bullet)$ are also exact.

Proof. It is easy to check that our sequence is exact at $\Omega^0(U)$. We must show that it is exact at any $\Omega^i(U)$ with $i \geq 1$. There is some homotopy $F : U \times I \to U$ such that $F_0 = c_x$ and $F_1 = \mathrm{id}_U$. Let $\omega \in \Omega^i(U)$. We have that $(d\sigma + \sigma d)\omega = F_1^*\omega - F_0^*\omega = \omega - 0 = \omega$. Hence $d\sigma + \sigma d = \mathbb{1}_{\Omega^i(U)}$. $\square$

Corollary 34. If $\mathcal{U}$ is a finite good cover of M, then $H_{\mathrm{dR}}^*(M) \cong \check{H}^*(\mathcal{U}; \mathbb{R})$.

Theorem 29. (De Rham) Let M be a smooth manifold and let $(\Omega^*(M), d)$ denote the cochain complex of differential forms. Then $H^*_{\mathrm{dR}}(M) \equiv H^*(\Omega^*(M), d)$. If M is paracompact, then

$$H^*_{\mathrm{dR}}(M) \cong H^*(M; \mathbb{R})$$

as graded rings.

Proof. Choose a finite good cover $\mathcal{U}$ of M. We have just proven that $H^*_{\mathrm{dR}}(M) \cong \check{H}^*(\mathcal{U}; \mathbb{R})$. By a similar argument, we can also show that $H^*(M; \mathbb{R}) \cong \check{H}^*(\mathcal{U}; \mathbb{R})$. $\qquad\square$

4.6 Lecture 24

5 Sheaves on spaces

Definition. Let X be a space and $\mathbf{Op}(X)$ denote the category of open sets in X. A *presheaf on X* is a functor $F : \mathbf{Op}(X)^{\mathrm{op}} \to \mathbf{Ab}$ such that $F(\emptyset) = 0$. If $V \subset X$ is open, then any $s \in F(V)$ is called a *section of U*. If $i : U \hookrightarrow V$, then $F(i) : F(V) \to F(U)$ is called a *restriction morphism* and is denoted by r_{UV}. Let $r_{UV}(s) := s \restriction_U$. Let $\mathbf{PreSh}_X$ denote the category of presheaves on X.

Remark 30. (Čech cohomology) We can build a cohomology theory of presheaves as follows. Let X be a space with $\mathcal{U}$ an open cover. Let F be a presheaf on X. Let $\check{C}(\mathcal{U}, F)$ denote the chain complex

$$\prod_{\alpha_0} F(U_{\alpha_0}) \xrightarrow{\delta} \prod_{\alpha_0 \alpha_1} F(U_{\alpha_0 \alpha_1}) \xrightarrow{\delta} \prod_{\alpha_0 \alpha_1 \alpha_2} F(U_{\alpha_0 \alpha_1 \alpha_2}) \xrightarrow{\delta} \cdots$$

where for any $f = (\; \underbrace{f_{\alpha_0 \ldots \alpha_p}}_{\in F(U_{\alpha_0 \ldots \alpha_p})} \;)$, we take $(\delta f)_{\alpha_0 \ldots \alpha_{p+1}} \equiv \sum_{i=0}^{p+1} (-1)^i f_{\alpha_0 \ldots \hat{\alpha}_i \ldots \alpha_{p+1}} \restriction_{U_{\alpha_0 \ldots \alpha_{p+1}}}$. Define the *p-th Čech cohomology group* as

$$\check{H}^p(X, F) = \varinjlim_{\mathcal{R}} \check{H}^p(\mathcal{U}, F)$$

where $\mathcal{R}$ denotes the set of all open covers of X ordered by refinement.

Definition. A presheaf F on X is a *sheaf* if for any open $U \subset X$ and any open cover $\{U_\alpha\}$ of U, we have an exact sequence

$$0 \to F(U) \to \prod_\alpha F(U_\alpha) \xrightarrow{\tau} \prod_{\alpha_0 \alpha_1} F(U_{\alpha_0 \alpha_1})$$

where $(\tau f)_{\alpha_0 \alpha_1} \equiv f_{\alpha_1} \restriction_{U_{\alpha_0 \alpha_1}} - f_{\alpha_0} \restriction_{U_{\alpha_0 \alpha_1}}$. Let $\mathbf{Sh}_X$ denote the category of sheaves on X, which is a full subcategory of $\mathbf{PreSh}_X$.

Example 49.

1. If X is a manifold, then the assignment $U \mapsto \Omega^q(U)$ defines a sheaf. Indeed, let $g, f \in \Omega^q(U)$ such that $f \restriction_{U_\alpha} = f \restriction_{U_\alpha}$ for any α. Then $g = f$. Moreover, if $f_\alpha \in \Omega^q(U_\alpha)$ satisfies $f_\alpha \restriction_{U_{\alpha\beta}} = f_\beta \restriction_{U_{\alpha\beta}}$ for every β, then there is some $f \in \Omega^q(U)$ such that $f \restriction_{U_\alpha} = f_\alpha$.

2. Given an abelian group A, the *constant presheaf with value A* is given by $F(U) = A$. This is not a sheaf. Let U and V be any two spaces. Then $\{U, V\}$ is a cover for $U \coprod V$, but

$$0 \to F(U \coprod V) \to F(U) \times F(V) \to F(U \cap V)$$

   is not exact.

3. Given a set A endowed with the discrete topology, the *constant sheaf with value A* is given by

$$U \mapsto \{f : U \to A \mid f \text{ locally constant}\} = \{f : U \to A \mid f \text{ continuous}\}.$$

   This is denoted by $\underline{A}$.

4. If X is a holomorphic manifold, then we have a sheaf $\mathcal{O}(-)$ of holomorphic functions on open subsets of X.

5. The assignment sending each U to the group $C(U)$ of functions $U \to \mathbb{R}$ is a sheaf.

6. The assignment sending each U to the group $C_b(U)$ of bounded continuous functions $U \to \mathbb{R}$ is a presheaf but not a sheaf. Indeed, for each $i \in \mathbb{Z}$, define $f_i : U_i \to \mathbb{R}$ by $f_i(x) = x$ where $U_i := (i-1, i+1) \subset \mathbb{R}$. Each $f_i \in C_b(U_i)$, but you cannot glue the f_i to a global bounded continuous function.

Definition. Let F be a presheaf on X and $x \in X$. Define *the stalk F_x of F at x* as $\varinjlim_{U \ni x} F(U)$.

Example 50.

1. For any $x \in X$, $\underline{A}_x = A$.

2. The *germs of continuous functions at x* are precisely the elements of
$$C_x = \{(U, f) \mid x \in U, \ f \in C(U)\} \big/ {\sim}$$
where $(U, f) \sim (V, g)$ if $f = g$ on $U \cap V$.

3. Let $X = \mathbb{R}$. Let $C^\infty(-)$ denote the sheaf of smooth functions on X. Then we have an exact sequence
$$0 \to \text{(flat functions)} \to C_0^\infty \to \mathbb{R}[[x]] \to 0.$$

4. Let $\mathcal{A}$ denote the sheaf of real analytic functions. Then $\mathcal{A}_0 \cong \mathbb{R}\{x\}$, the ring of real analytic functions.

Definition. Let F be a presheaf on X. Let $U \subset X$ be open and $s \in F(U)$. Define $\bar{s} : U \to \coprod_{x \in X} F_x$ by $x \mapsto (x, (U, s))$. Define the *étalé space of F* as
$$\text{Ét}(F) = \Big(\coprod_{x \in X} F_x, \tau \Big)$$
where
$$\tau = \{S \subset \text{Ét}(F) \mid \bar{s}^{-1}(S) \text{ is open, } s \in F(U), \ U \subset X\}.$$
Equivalently, τ is generated by sets of the form $\text{Ét}(U, s) := \{(U, s_x) \mid x \in U\}$.

Proposition 31. The natural projection $\pi : \text{Ét}(F) \to X$ is a local homeomorphism.

Note 50. We have a functor $\mathbf{PreSh}_X \xrightarrow{\ +\ } \mathbf{Sh}_X$ given by $F \mapsto F^+$ where F^+ is given by
$$U \mapsto \{s : U \to \text{Ét}(F) \mid \pi s(x) = x \text{ and } s \text{ is continuous}\}.$$
This is left adjoint to the forgetful functor $\mathbf{Sh}_X \to \mathbf{PreSh}_X$.

5.1 Lecture 25

Lemma 43. Let $F, G \in \text{ob}\,\mathbf{Sh}_X$ and $f, g : F \to G$.

(a) If $f_x = g_x$ for every $x \in X$ where $g_x, f_x : F_x \to G_x$, then $f = g$.

(b) $f_x : F_x \to G_x$ is injective for every x if and only if $f_U : F(U) \to G(U)$ is injective for every open $U \subset X$.

(c) $f_x : F_X \to G_x$ is an isomorphism if and only if f is an isomorphism.

Proof.

(a) Consider the commutative square

$$\begin{array}{ccc} F(U) & \xrightarrow{\ \alpha\ } & \prod_{x \in U} F_x \\ \downarrow & & \downarrow{\scriptstyle \prod_{x \in U} f_x = \prod_{x \in U} g_x} \\ G(U) & \xrightarrow[\ \beta\ ]{} & \prod_{x \in U} G_x \end{array}.$$

Note that α and β are injective by sheaf-hood. Since $f_x = g_x$ for every $x \in U$, we can replace $f(U)$ by $G(U)$ and still make our square commute.

(b) This follows from our commutative square.

(c) Part (b) shows that $f(U) : F(U) \to G(U)$ is injective. Hence we must show that it's surjective. Let $s \in G(U)$. For any $x \in U$, there exist $U_x \ni x$ and $s^x \in F(U_x)$ such that $f(s^x)_x = s_x$. Now use sheafiness to glue the s^x together.

$\square$

Proposition 32. There exists a natural transformation $\mathbb{1} \xrightarrow{\ U\ } +$ that is an isomorphism on stalks, i.e., $U_x : F_x \to F_x^+$ is an isomorphism for every x.

Definition. Given any $f : F \to G$ with $F, G \in \mathrm{ob}\,\mathbf{Sh}_X$, let $\ker f(U) \equiv \ker(f(U) : F(U) \to G(U))$ for each open $U \subset X$. Then $\ker f$ is a sheaf. Let $\mathrm{coker}^- f(U) \equiv \mathrm{coker}(f(U) : F(U) \to G(U))$. This induces a presheaf $\mathrm{coker}^- f$. Finally, let $\mathrm{coker}\, f \equiv \mathrm{coker}^- f^+$.

Proposition 33. $\mathbf{Sh}_X$ is an abelian category.

Exercise 10. There are no projectives in $\mathbf{Sh}_X$.

Proposition 34. (Baer) Let I be a right R-module. Then I is injective if and only if for any right ideal $J \trianglelefteq R$, any map $\alpha : J \to I$ extends to a map $\tilde{\alpha} : R \to I$.

Proof. This requires Zorn's lemma. $\square$

Corollary 35. There are *enough injectives* in $R^{\mathrm{op}} - \mathbf{Mod}$, i.e., any object can be embedded in an injective object.

Proposition 35. There are enough injectives in $\mathbf{Sh}_X$.

Proof. If $\{I_x\}_{x \in X}$ denotes a family of abelian groups , then define $\underline{I}(U) = \prod_{x \in U} I_x$ and $\mathrm{Hom}_{\mathbf{Sh}}(F, \underline{I}) = \prod_{x \in X} \mathrm{Hom}(F_x, I_x)$. As a result, if I_x is injective (i.e., divisible), then I will be injective. Given any sheaf F, choose I_x injective such that $F_x \hookrightarrow I_x$. By doing this, we can form an injective object I so that $0 \to F \to I$ is exact. $\square$

Definition. Given any diagram of sheaves

$$0 \to A \xrightarrow{\ i\ } B \xrightarrow{\ j\ } C \to 0,$$

we say that this is *exact* if $0 \to A_x \xrightarrow{\ i_x\ } B_x \xrightarrow{\ j_x\ } C_x \to 0$ is exact for each $x \in X$.

Proposition 36. If $0 \to A \to B \to C \to 0$ is exact in $\mathbf{Sh}_X$, then $0 \to A(X) \to B(X) \to C(X)$ is exact in $\mathbf{Ab}$.

Example 51. Let $X = \mathbb{C}^\times$. Then

$$0 \to \underline{\mathbb{Z}} \xrightarrow{\ i\ } \mathcal{O}_X \xrightarrow{\ g\ } \mathcal{O}_X^X \to 0$$

is exact where $\mathcal{O}_X^X(U) \equiv \{\varphi : U \to \mathbb{C} \text{ holomorphic} \mid \varphi(x) \neq 0 \text{ for any } x \in U\}$ and $g : f \mapsto e^{2\pi i f}$.

Proof. Clearly, i is injective. If $f \in \mathcal{O}_X(U)$ and $e^{2\pi i f} = 1$, then $f : U \to \mathbb{C}$ is locally constant and $f(x) \in \mathbb{Z}$. If $\varphi \in \mathcal{O}_{X,x}^X$, then there exist a small open simply connected set U and $\tilde{\varphi} \in \mathcal{O}_X^X(U)$ such that $\tilde{\varphi}_x = \varphi$ and $\log \tilde{\varphi}_x$ exists. Globally, however, $z \in \mathcal{O}_X^X(\mathbb{C}^\times)$ cannot be hit by $e^{2\pi i \varphi}$. $\square$

Definition. Let F be a sheaf on X. A *resolution of F* is an exact sequence of the form

$$0 \to F \to F^0 \to F^1 \to F^2 \to \cdots .$$

Example 52.

1. Let X be a smooth manifold. Then

$$0 \to \mathbb{R} \to \Omega_X^0 \xrightarrow{d} \Omega_X^1 \xrightarrow{d} \Omega_X^2 \to \cdots$$

   is a resolution of $\mathbb{R}$.

   Proof. This is precisely Poincaré's lemma. $\qquad\square$

2. Let X be locally contractible. Define $C^p(U)$ as the singular $\mathbb{Z}$-valued p-cochains in the open $U \subset X$. This defines a presheaf on X. Let C_X^p denote its sheafification. Then

$$0 \to \underline{\mathbb{Z}} \to C_X^0 \xrightarrow{\delta} C_X^1 \xrightarrow{\delta} C_X^2 \to \cdots$$

   is a resolution.

Definition. (Sheaf cohomology) To derive $\operatorname{Ext}_{\mathbf{Sh}}^*(F, G)$, take an injective resolution $I^\bullet$ of G and then form the complex

$$\operatorname{Hom}_{\mathbf{Sh}}(F, I^0) \to \operatorname{Hom}_{\mathbf{Sh}}(F, I^1) \to \cdots .$$

Then define $\operatorname{Ext}_{\mathbf{Sh}_X}^*(F, G)$ as the cohomology of this complex. Note that $\operatorname{Hom}_{\mathbf{Sh}}(\mathbb{Z}, I^\bullet) = I^\bullet(X)$. We define the cohomology $H^*(X, G)$ of G as $\operatorname{Ext}_{\mathbf{Sh}}(\mathbb{Z}, G)$. Standard homological algebra shows that this si independent of our choice of injective resolution.

Definition. A sheaf F on X is *flabby* if for any U, $F(X) \to F(U)$ is surjective. Equivalently, a sheaf F on X is flabby if $F(V) \to F(U)$ is surjective for any inclusion $U \subset V$.

Example 53. (Godement's construction) Given any sheaf G, define a new sheaf $\operatorname{Gd}(G)$ by

$$\operatorname{Gd}(G)(U) = \prod_{x \in U} G_x$$
$$\operatorname{Gd}(G)(i : U \hookrightarrow V) = (s \mapsto s \upharpoonright_V)$$

.

Then we have an exact sequence $0 \to G \to \operatorname{Gd}(G) \to H_0 \to 0$ where $H_0 \equiv \operatorname{coker}(G \to \operatorname{Gd}(G))$. From this, we can form the exact sequence $0 \to H_0 \to \operatorname{Gd}(H_0) \to H_1 \to 0$ where $H_1 \equiv \operatorname{coker}(H_0 \to \operatorname{Gd}(H_0))$, and so on. What results is a resolution

$$0 \to \operatorname{Gd}(G) \to \operatorname{Gd}(H_0) \to \operatorname{Gd}(H_1) \to \cdots .$$

Note that $\operatorname{Gd}(G)$, as well as each sheaf $\operatorname{Gd}(H_i)$, is flabby.

Definition. A sheaf F on X is *soft* if for any closed set C, the map $F(X) \to F(C)$ is surjective in X where $F(C) \equiv \varinjlim_{U \supset C} F(U)$.

Example 54. Ω_X^0 is soft but not flabby.

5.2 Lecture 26

Lemma 44.

1. Any injective sheaf is flabby.

2. If $0 \to E \to F \to G \to 0$ is an exact sequence of sheaves and E is flabby, then $0 \to E(X) \xrightarrow{\iota} F(X) \xrightarrow{j} G(X) \to 0$ is exact. (Note that $0 \to E(X) \to F(X) \to G(X)$ is exact automatically.)

Proof.

1. Let I be injective, We can embed I in a flabby sheaf F via a map i. Since I is injective, we get a map ρ such that $\rho i = \mathbb{1}_I$. For any open $U \subset X$, we have a commutative diagram

$$
\begin{array}{ccc}
F(X) & \xrightarrow{r_{UX}} & F(U) \\
\rho_X \downarrow & & \downarrow \rho_U \\
I(U) & \longrightarrow & I(U)
\end{array} \ .
$$

Note that r_{UX} is surjective because F is flabby and that both ρ_X and ρ_U are surjective because $\rho i = \mathbb{1}_I$. Hence s_{UX} is surjective.

2. Let $g \in G(X)$ We want to show that there exists $f \in F(X)$ with $\iota f = g$. Let $\mathcal{A} := \{(U, u) \mid U \subset X \text{ open}, u \in F(U) \text{ with } g(u) = g \restriction_U\}$. We see that $\mathcal{A}$ is partially ordered by $\leq$ where $(U_1, u_1) \leq (U_2, u_2)$ if $U_1 \subset U_2$ and $u_1 = u_2 \restriction_{U_1}$. It also satisfies the hypotheses of Zorn's lemma. so that there is some maximal element (U, u) of $\mathcal{A}$. Suppose, towards a contradiction, that $U \neq X$. Choose any $x \in X \setminus U$ and choose a neighborhood $V \ni x$ and $x \in F(V)$ with $j(v) = s \restriction_V$. Then we have that

$$
j(\underbrace{r_{V \cap U, U}(u) - r_{V \cap U, V}(v)}_{\tilde{r}}) = 0
$$

in $G(U \cap V)$. Thus, $\tilde{r}$ comes from $E(U \cap V)$. Since E is flabby, $\tilde{r}$ extends to a section $\tilde{\tilde{r}}$ in $E(V)$. Consider $v + \tilde{\tilde{r}}$. Observe that $u \restriction_{U \cap V} = v + \tilde{\tilde{r}} \restriction_{U \cap V}$, and thus these piece together by the sheaf property to a section $\tilde{u}$ in $F(U \cup V)$ such that $j(\tilde{u}) = g \restriction_{\tilde{U}}$. This is a contradiction.

$\square$

Proposition 37. If $0 \to E \to F \to G \to 0$ is exact and both E and F are flabby, then G is flabby.

Lemma 45. If F is flabby, then $H^n(X, F) = 0$ for each $n \geq 1$.

Proof. Let $0 \to F \to I \to G \to 0$ be exact where I is injective (hence flabby). Then G is flabby. We have a LES

$$
H^0(X, F) \to H^0(X, I) \to H^0(X, G) \to H^1(X, F) \to H^1(X, I),
$$

where the map $H^0(X, I) \to H^0(X, G)$ is surjective since F is flabby and $H^1(X, I) = 0$ since I is injective. Therefore, $H^1(X, F) = 0$.

Assume, inductively, that we have shown that $H^k(X, F) = 0$ where $0 < k < n$ for any flabby sheaf F. Then $H^{n-1}(X, G) = 0$. since G is flabby. Also, $H^n(X, I) = 0$ since I is injective. In light of the exact sequence $H^{n-1}(X, G) \to H^n(X, F) \to H^n(X, I)$, it follows that $H^n(X, F) = 0$. $\square$

Lemma 46. If E is a sheaf on X and

$$
0 \to E \to F^0 \to F^1 \to F^2 \to \cdots
$$

is a flabby resolution, then $H^*(X, E) \cong H^*(\Gamma(X, F^\bullet))$ where $\Gamma(X, -)$ denotes the global section functor.

Proof. We can form an augmented double complex of sheaves

$$
\begin{array}{ccccccc}
\vdots & & \vdots & & \vdots & & \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,2} & \longrightarrow & I^{1,2} & \longrightarrow & I^{2,2} & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,1} & \longrightarrow & I^{1,1} & \longrightarrow & I^{2,1} & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,0} & \longrightarrow & I^{1,0} & \longrightarrow & I^{2,0} & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
0 \longrightarrow E \longrightarrow F^0 & \longrightarrow & F^1 & \longrightarrow & F^2 & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
0 & & 0 & & 0 & &
\end{array}
$$

such that each $I^{i,\bullet}$ is an injective resolution of F^i. After applying the global section functor to this complex, we obtain a new augmented double complex

$$
\begin{array}{ccccccc}
\vdots & & \vdots & & \vdots & & \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,2}(X) & \longrightarrow & I^{1,2}(X) & \longrightarrow & I^{2,2}(X) & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,1}(X) & \longrightarrow & I^{1,1}(X) & \longrightarrow & I^{2,1}(X) & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,0}(X) & \longrightarrow & I^{1,0}(X) & \longrightarrow & I^{2,0}(X) & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
0 \longrightarrow E(X) \longrightarrow F^0(X) & \longrightarrow & F^1(X) & \longrightarrow & F^2(X) & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
0 & & 0 & & 0 & &
\end{array}
$$

The columns of our new complex are acyclic.

Claim 4. $\mathrm{Tot}(I^{\bullet,\bullet}, d_{\mathrm{Tot}})$ forms an injective resolution of E.

Proof. Note that the direct sum of two injective abelian groups is injective.[2] Consider the sequence

$$
0 \longrightarrow E(X) \xrightarrow{g \circ f} I^{0,0} \xrightarrow{\delta + d} I^{1,0} \oplus I^{0,1} \longrightarrow I^{2,0} \oplus I^{1,1} \oplus I^{0,2} \longrightarrow \cdots
$$

where $f : E(X) \to F^0(X)$ and $g : F^0 \to I^{0,0}$. Clearly $g \circ f$ is injective. Moreover, since $\mathrm{Tot}(I^{\bullet,\bullet}$ is bounded and has exact columns, it follows that each term of our sequence after $I^{0,0}$ is exact. Thus, it remains to verify that out sequence is exact at $I^{0,0}$.

Suppose that $x \in \ker \delta + d$. Then $(\delta(x), d(x)) = (0,0)$, so that $g(y) = x$ for some $y \in F^0(X)$. Since g is injective and

$$
g(\delta(y)) = \delta(g(y)) = \delta(x) = 0
$$

---

[2]One can find online that the coproduct of two injective R-modules is injective if and only if R is Noetherian.

, we see that $\delta(y) = 0$. Hence there is some $y' \in E(X)$ such that $f(y') = y$. This implies that $g(f(y')) = x$, which thus belongs to $\operatorname{im} g \circ f$.

Conversely, suppose that $x = g(f(y))$ for some $y \in E(X)$. Then

$$
\begin{aligned}
\delta + d(g(f(y))) &= (\delta(g(f(y))), d(g(f(y)))) \\
&= (g(\delta(f(y))), d(g(f(y)))) \\
&= (0, 0)
\end{aligned}
$$

since $\delta \circ f = 0 = d \circ g$. Therefore, $x \in \ker \delta + d$. $\qquad\square$

It follows that
$$
H^*(X, E) \cong H^*(I^{\bullet,\bullet}, d, \delta) \cong H^*(\Gamma(X, F^\bullet)).
$$
$\qquad\square$

Remark 31. Let X be a space and $\underline{R}$ be a sheaf of rings over X. Let $\mathbf{Sh}_R(X)$ denote the category of sheaves of R-modules on X. Let M be a sheaf of R-modules and consider the commutative diagram

$$
\begin{array}{ccc}
\underline{R}(U) \times M(U) & \longrightarrow & M(U) \\
\downarrow & & \downarrow \\
\underline{R}(V) \times M(V) & \longrightarrow & M(V)
\end{array}
$$

Flabbiness still suffices to compute $H^*(X, M) \equiv \operatorname{Ext}_{\mathbf{Sh}_R(X)}(R, M)$. Nevertheless, it does not suffice to compute $\operatorname{Ext}_{\mathbf{Sh}_R(X)}(N, M)$.

Proposition 38. Let E be soft and $0 \to E \to F \to G \to 0$ be exact. Then $0 \to E(X) \to F(X) \to G(X) \to 0$ is exact.

Definition. Let X be paracompact. A sheaf E on X is *fine* if for any locally finite cover $\{U_\alpha\}$, there exists a family of homomorphisms $\lambda_\alpha : E \to E$ such that

- $\sum_\alpha \lambda_\alpha = 1$ and
- for each α, there is some neighborhood N of $U_\alpha{}^c$ such that $\lambda_\alpha(x) = 0$ whenever $x \in N$.

Proposition 39.

1. Any flabby sheaf is soft.

2. If $0 \to E \to F \to G \to 0$ is exact and both E and F are soft, then G is soft.

3. If E is soft, then $H^k(X, E) = 0$ for any $k > 0$.

4. Let
$$
0 \to E \to F^0 \to F^1 \to \cdots
$$
be a resolution where each F^i is soft. Then $H^*(X, E) \cong H^*(F^\bullet(X))$.

Example 55.

1. The sheaf on X of continuous functions is soft.

2. If X is a smooth manifold, then the sheaf on X of smooth functions is soft due to the existence of bump functions.

Corollary 36. The de Rham theorem.

Proof. We know that each Ω_X^i is soft. Moreover, the sequence

$$0 \to \underline{\mathbb{R}}_X \to \Omega_X^0 \xrightarrow{d} \Omega_X^1 \xrightarrow{d} \Omega^2(X) \to \cdots$$

is exact by the Poincaré lemma. $\qquad\square$

Note 51. Let $f : X \to Y$ be a continuous function. Let E be a sheaf on X and G be a sheaf on Y. We define $f_*E \in \mathbf{Sh}_Y$ by

$$(f_*E)(U) = E(f^{-1}(U)).$$

Also, we define $f^*G \in \mathbf{Sh}_X$ by

$$f^*G(V) = (\varinjlim_{U \supset f(V)} G(U))^+.$$

Consider the commutative square

$$\begin{array}{ccc}
X \times_Y \text{Ét}(G) & \longrightarrow & \text{Ét}(G) \\
\pi \downarrow & & \downarrow \pi \\
X & \xrightarrow{\quad f \quad} & Y
\end{array} \ .$$

Then $f^*G(V)$ equals the section over V of $\pi : X \times_Y \text{Ét}(G) \to V$.

Proposition 40. $(f^*G)_x \cong G_{f(x)}$.

Corollary 37. If $0 \to E \to F \to G \to 0$ is an exact sequence in $\mathbf{Sh}_Y$, then $0 \to f^*E \to f^*F \to f^*G \to 0$ is exact in $\mathbf{Sh}_X$.

Proposition 41. (f^*, f_*) is an adjoint pair.

Corollary 38. f_* takes injectives to injectives.

Proof. Let I be injective. Let $0 \to E \to F \to G \to 0$ be an exact sequence in $\mathbf{Sh}_Y$. We must show that

$$0 \to \text{Hom}_{\mathbf{Sh}_Y}(G, f_*I) \to \text{Hom}_{\mathbf{Sh}_Y}(F, f_*I) \to \text{Hom}_{\mathbf{Sh}_Y}(E, f_*I) \to 0$$

is exact. But by adjointness, we see that

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \text{Hom}_{\mathbf{Sh}_Y}(G, f_*I) & \longrightarrow & \text{Hom}_{\mathbf{Sh}_Y}(F, f_*I) & \longrightarrow & \text{Hom}_{\mathbf{Sh}_Y}(E, f_*I) & \longrightarrow & 0 \\
& & \downarrow \cong & & \downarrow \cong & & \downarrow \cong & & \\
0 & \longrightarrow & \text{Hom}_{\mathbf{Sh}_Y}(f^*G, I) & \longrightarrow & \text{Hom}_{\mathbf{Sh}_Y}(f^*F, I) & \longrightarrow & \text{Hom}_{\mathbf{Sh}_Y}(f^*E, I) & \longrightarrow & 0
\end{array}$$

is commutative. Since I is injective, it follows that the bottom row is exact. Hence the top row is exact as well, as required. $\qquad\square$

Corollary 39. Our proof shows that any right adjoint preserves injectives.

Remark 32. Let $f : X \to \mathsf{pt}$ be a map. Then $f_*E = \Gamma(X, E)$ for any sheaf E on X. If $f : X \to B$ is a fiber bundle, then

$$f_*E(U \subset B) = E(\underbrace{f^{-1}(U)}_{U \times B}).$$

5.3   Lecture 27

Definition. Let R be a sheaf of rings on X. A *sheaf F of R-modules* is a sheaf on X such that for any inclusion $V \subset U$ of open sets in X,

- $F(U)$ is an $R(U)$-module and

- if $f \in R(U)$ and $g \in F(U)$, then $(fg) \restriction_V = f \restriction_V g \restriction_V$.

Proposition 42. Let Z and W be closed in the space X. Let F be sheaf on X. If $s \in F(Z)$ and $t \in F(W)$ satisfy $s \restriction_{Z \cap W} = t \restriction_{Z \cap W}$, then there exists a unique $w \in F(Z \cup W)$ extending s and t.

Lemma 47. If R is a soft sheaf of rings on X, then any sheaf F of R-modules is soft.

Proof. Let $C \subset X$ be closed and let $s \in F(C)$. There exist a neighborhood U of C and a section $s' \in F(U)$ that represents s.

Let $L \subset U$ be a compact set in X such that $\operatorname{Int}(L) \supset C$. Let t be the section equal to 1 on C and t' be the section equal to 0 on ∂L. By our previous proposition, we can glue these to get a section w over $C \cup \partial L$. By softness, we can extend w to a section $w' \in R(L)$. Again, we can glue w and the section equal to 0 on $\operatorname{cl}(U \setminus L)$ to get a section $m \in R(U)$.

Note that
$$(m \cdot s') \restriction_C = m \restriction_C \cdot s' \restriction_C = s.$$

Now, glue $(m \cdot s') \restriction_L$ and the section y which is equal to 0 on $\operatorname{cl}(C \setminus L)$ to get a section $y' \in F(X)$ such that $y' \restriction_C = s$. This proves that the homomorphism $F(X) \to F(C)$ is surjective. $\qquad\square$

Corollary 40. If X is a smooth manifold, then the sheaf $\Omega^i(X)$ of i-forms is soft because it is a module over the sheaf of smooth functions.

Note 52. Let X be a smooth manifold. We have that $0 \to \underline{\mathbb{R}} \to \Omega_X^\bullet$ is a soft resolution and that $\underbrace{H^*(X, \underline{\mathbb{R}})}_{\text{Čech cohom.}} \cong$

$H^*(\Omega^\bullet(X), d)$.

Note 53. Let A be a ring. For each $p \in \mathbb{N}$, define the presheaf $U \subset X \mapsto \{f : \operatorname{Sing}_p(U) \to A\}$. Sheafify this to get $\mathfrak{S}^p(A)$. Define the map of sheaves $\delta : \mathfrak{S}^p(A) \to \mathfrak{S}^{p+1}(A)$ by

$$\delta_U(f : \operatorname{Sing}_p(U) \to A)(\sigma : \Delta^{p+1} \to A) = \sum_{i=0}^{p+1} (-1)^i f\sigma \restriction_{\partial_i \Delta^{p+1}}$$

where $\partial_i \Delta^p = [e_0, \ldots, e_{i-1}, \hat{e}_i, e_{i+1}, \ldots, e_p]$. This induces a resolution $0 \to \underline{A} \to \mathfrak{S}^\bullet(A)$.

Likewise, if X is a smooth manifold, then define the sheaf $U \mapsto \{f : \operatorname{Sing}_p^\infty(U) \to A\}$ where $\operatorname{Sing}_p^\infty(U)$ denotes the free abelian group on the set of smooth maps $\sigma : \Delta^p \subset \mathbb{R}^{p+1} \to U$, i.e., all σ with a smooth extension to some neighborhood of Δ^p. Sheafify this to get $\mathfrak{S}_\infty^p(A)$. We still have a resolution

$$0 \to \underline{A} \to \mathfrak{S}_\infty^\bullet(A).$$

Lemma 48. Let X be a smooth manifold. Define the map $I^p : \Omega_X^p \to \mathfrak{S}_\infty^p(\mathbb{R})$ by

$$I^p(\omega \in \Omega^p(U))(\sigma \in \operatorname{Sing}_p^\infty(U)) = \int_{\Delta^p} \sigma^* \omega.$$

Then $I^\bullet$ is a chain map $\Omega_X^\bullet \to \mathfrak{S}_\infty^\bullet(\mathbb{R})$.

Proof. Let $\omega \in \Omega^p(U)$ and $\sigma \in \mathrm{Sing}_{p+1}^{\infty}(U)$, We can apply Stokes' theorem to get

$$
\begin{aligned}
I(d\omega)(\sigma) &= \int_{\Delta^{p+1}} \sigma^* d\omega \\
&= \int_{\Delta^{p+1}} d\sigma^* \omega \\
&= \sum_{i=0}^{p+1} (-1)^i \int_{\partial_i \Delta^{p+1}} \sigma^* \omega \\
&= \delta(I(\omega)).
\end{aligned}
$$

$\square$

Theorem 30. (De Rham) $I^{\bullet}$ induces an isomorphism $I : H^p(\Omega^{\bullet}(X)) \to H^p(\mathfrak{S}_{\infty}^{\bullet}(X; \mathbb{R}))$ for each p.

Proof. It suffices to show that $\mathfrak{S}_{\infty}^{\bullet}(X; \mathbb{R})$ is soft. We show that it is, in fact, flabby. Since each $\mathfrak{S}_{\infty}^p(X; \mathbb{R})$ is a module over $\mathfrak{S}_{\infty}^0(X; \mathbb{R})$, it suffices to show that $\mathfrak{S}_{\infty}^0(X; \mathbb{R})$ is flabby. Note that if $U \subset X$ is open, then $\mathfrak{S}_{\infty}^0(U; \mathbb{R}) = \{f : \mathrm{Sing}_0^{\infty}(U) \to \mathbb{R}\}$, which is precisely the set of all maps $\mathbb{Z}[U] \to \mathbb{R}$. Since we can extend any such function to a map $\mathbb{Z}[X] \to \mathbb{R}$, we see that $\mathfrak{S}_{\infty}^0(X; \mathbb{R})$ is flabby. $\square$

Theorem 31. Let X be paracompact and let F be a sheaf on X. Suppose that $\mathcal{U} \coloneqq \{U_\alpha\}$ is an open cover of X such that $U_{\alpha_0 \alpha_1 \dots \alpha_p}$ either is empty or has $H^k(U_{\alpha_0 \alpha_1 \dots \alpha_p}, F) = 0$ for any $k > 0$. Then $H^*(X, F) \cong \check{H}^*(\mathcal{U}, F)$.

Corollary 41. If X is locally contractible and paracompact, then $\underbrace{H^*(X; \mathbb{Z})}_{\text{singular}} \cong H^*(X, \underline{\mathbb{Z}})$.

Note 54. Let $f : X \to Y$ be a map of spaces and F be a sheaf on X. Define the *i-th right derived functor* as
$$
\mathcal{R}^i f_* F = (U \subset Y \mapsto H^i(f^{-1}(U), F))^+.
$$

This is <mark>equivalent</mark> to the sheaf $\underline{H}^i(f_* I) \equiv (U \subset Y \mapsto H^i(\Gamma(U, f_* I)))$ where $I^{\bullet}$ is an injective resolution of F. We can view $\mathcal{R} f_* F$ as a complex
$$
f_* I^0 \to f_* I^1 \to f_* I^2 \to \cdots
$$

of injective sheaves on Y.

Furthermore, given a complex of sheaves $(C^{\bullet}, \delta)$ on X, the *cohomology sheaf* $\underline{H}^i(C^{\bullet})$ is given by the sheafification of $U \mapsto H^i(C^{\bullet}(U), \delta)$. Note that $\underline{H}^i(C^{\bullet})_x = H^i(C_x^{\bullet}, \delta)$ for any $x \in X$.

Consider the augmented double complex

$$
\begin{array}{ccccccc}
\vdots & & \vdots & & \vdots & & \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,1} & \longrightarrow & I^{1,1} & \longrightarrow & I^{2,1} & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
I^{0,0} & \longrightarrow & I^{1,0} & \longrightarrow & I^{2,0} & \longrightarrow & \cdots \\
\uparrow & & \uparrow & & \uparrow & & \\
C^o & \longrightarrow & C^1 & \longrightarrow & C^2 & \longrightarrow & \cdots
\end{array}
$$

where each $C^i \to I^{i,\bullet}$ is an injective resolution. Define the *i-th cohomology group* as

$$
\mathbb{H}^i(X, C^{\bullet}) = H^i(\mathrm{Tot}\,\Gamma(X, I^{\bullet, \bullet})).
$$

We have that

$$
\mathbb{H}^*(Y, \mathcal{R} f_* F) \cong H^*(X, F).
$$

6 Vector bundles

Definition. Let X be a space. A *vector bundle on X* is a triple (X, E, π) such that

- E is a space (called the *total space*),

- $\pi : E \to X$ is continuous surjection,

- for any $x \in X$, there exist an open $U \ni x$ in X and a homeomorphism $\varphi_U : \pi^{-1}(U) \to U \times E_0$ (called a *local trivialization*) where E_0 is a vector space,

- $\varphi_U \restriction_x : E_x := \pi^{-1}(x) \to \{x\} \times E_0$ is an isomorphism of vector spaces for each $x \in X$, and

- if $p_1 : U \times E_0 \to U$ denotes the first projection map, then

$$
\begin{array}{ccc}
\pi^{-1}(U) & \xrightarrow{\varphi_U} & U \times E_0 \\
& \searrow_{\pi} & \downarrow_{p_1} \\
& & U
\end{array}
$$

commutes.

We call the dimension of E_0 the *rank of the bundle*. If π is smooth and each φ_U is a diffeomorphism, then we say that E is a *smooth vector bundle on X*.

Example 56.

1. $X \times E_0$ is called the *trivial vector bundle*.

2. The Möbius strip, i.e., $[0, 1] \times \mathbb{R} / {\sim}$ where $(0, -t) \sim (1, t)$.

3. Let X be a smooth manifold. Then the tangent bundle TX is a vector bundle.

4. If G is a Lie group, then $TG \cong G \times T_0 G$ via $(L_g)_* \xi \leftarrow\!\shortmid (g, \xi)$ where L_g denotes left translation by g.

Note 55.

1. Let (X, E, π) be a vector bundle. Given two distinct points $x, y \in X$, we can find neighborhoods $U \ni x$, $V \ni y$ and homeomorphisms φ_U, φ_V. Consider the composition

$$
(U \cap V) \times E_0 \xrightarrow{\varphi_V^{-1}} \pi^{-1}(U \cap V) \xrightarrow{\varphi_U} (U \cap V) \times E_0.
$$

   Let $g_{UV}(x, e) = \varphi_U(\varphi_V^{-1}(x, e))$ for each $(x, e) \in (U \cap V) \times E_0$. Thus, we can write $g_{UV}(x, e) = (x, g_{UV}(x)(e))$ where $g_{UV}(x) : E_0 \to E_0$ is a linear isomorphism. Note that $g_{UU}(x) = \mathbb{1}_{E_0}$ for any $x \in U$ and that $g_{UV} g_{VW} = g_{UW}$. We call g_{UV} a *transition function for E*.

2. Let X be a smooth manifold and $\{U_\alpha\}_{\alpha \in I}$ be an open cover of X. Let the transition function $g_{\alpha\beta} : U_{\alpha\beta} \to \mathcal{L}(E_0)$ be smooth for any $\alpha, \beta \in I$ such that $g_{\alpha\alpha} = \mathbb{1}$ and $g_{\alpha\beta} g_{\beta\gamma} = g_{\alpha\gamma}$ on $U_{\alpha\beta\gamma}$. Then there exists a smooth vector bundle on X, namely

$$
\coprod_\alpha U_\alpha \times E_0 \big/ {\sim}
$$

   where $U_{\alpha_0\alpha_1} \times E_0 \ni (x, e) \sim (x, g_{\alpha_0\alpha_1}(x)(e)) \in U_{\alpha_0} \times E_0$. We call $\{U_\alpha\}$ a *trivializing cover*.

6.1 Lecture 28

Notation.

1. Let $\pi : E^{k/\mathbb{F}} \to X$ denote an $\mathbb{F}$-vector bundle of rank k.

2. Let $C^\infty(X; E)$ denote the space of smooth sections of a given smooth bundle (X, E, π).

Exercise 11. Let $\pi : E \to X$ be a smooth vector bundle.

1. Let $\{U_\alpha\}$ be an open cover of X and $\{g_{\alpha\beta}\}$ a collection of transition functions. Show that $C^\infty(X; E) \cong \{s_\alpha : U_\alpha \to \mathbb{R}^k \mid g_{\alpha\beta} s_\beta = s_\alpha\}$.

2. Consider $\mathbb{CP}^n$. There exists a rank one *tautological bundle* $\gamma \xrightarrow{\pi} \mathbb{CP}^n$, also known as the *complex line bundle*. We have that $\mathbb{CP}^n \equiv \mathbb{C}^{n+1} \setminus \{0\}/\mathbb{C}^\times = $ (lines through 0 in $\mathbb{C}^{n+1}$). If $l \subset \mathbb{C}^{n+1}$ is such a line, then let $\alpha_l = l$. Compute $g_{01} : U_{01} \to \mathbb{C}^\times = \mathrm{GL}_1(\mathbb{C})$. It should look like z^{-1}.

3. Consider the bundle γ^* on $\mathcal{O}(n)$, where the transition function is precisely z^n. Show that meromorphic functions on $\mathbb{CP}^1$ correspond to algebraic sections of $\mathcal{O}(n)$, which are precisely homogenous polynomial of degree n.

Note 56. We want to differentiate sections of a vector bundle. Let $s : X \to E$ be a section. Let

$$d_v s_x = \lim_{h \to 0} \frac{s(x + hv) - s(x)}{h}.$$

We need a way to compare points in different fibers. This leads to the notation of a *connection*. Define $\nabla : C^\infty(X; E) \to \Omega^1(X; E) \cong C^\infty(X; T^*X \otimes E)$ by $fs \mapsto df \otimes s + f\nabla s$ where $s \in C^\infty(X; E)$ and $f \in C^\infty(X)$. We have that $\nabla_v(s) = i_v \nabla s \in \Omega^1(X; E)$ and $\nabla_{fv}(s) = f\nabla_v(s)$.

On a trivial bundle, connections exist. Indeed, given $X \times V$ and $s : X \to V$, we see that $\nabla_0(s) = ds \in \Omega^1(X) \otimes V$. More generally, if $\omega \in \omega^1(X) \otimes \mathrm{End}(V)$, then $\nabla_0 + w$ is also a connection.

On e general vector bundle $\pi : E \to X$, take a local trivialization $E \upharpoonright_{U_\alpha} \to U_\alpha \times \mathbb{R}^k$ and put a connection ∇_α on $E \upharpoonright_{U_\alpha}$. Let $\{\lambda_\alpha\}$ be a patron of unity subordinate to the U_α. Set $\nabla = \sum_\alpha \lambda_\alpha \nabla_\alpha$. Thus, connections always exist.

Let $\pi : E^{k/\mathbb{R}} \to X$ be a vector bundle with a connection ∇. Let $x, y \in X$ and let $p(t)$ be a path from x to y. Let $e(t)$ be a section of E along $p(t)$. We say that $e(t)$ is *covariantly constant* or *parallel* if $\nabla_{\mathring{p}(t)} e(t) = 0$. Consider $E_x \ni e_0$. The we have a first-order ODE with initial condition $e(0) = e_0$ and $\nabla_{\mathring{p}(t)} e(t) = 0$. By Picard, there exists a unique solution $e(t)$. Thus, we have defined a map given by $h(p)(e_0) = e(1)$, so that $h(p) : E_x \to E_y$ is linear. We call h the *holonomy map*. We get

$$\nabla_v s(x) = \lim_{t \to 0} \frac{h(p_t)^{-1} s(p(t)) 0 s(x)}{t}$$

where p is any path with $p'(0) = v$.

Given $\pi : E \to X$ and $\nabla : \Omega^0(X; E) \to |omega^1(X; E)$, we can extend ∇ to a map $\nabla : \Omega^k(X; E) \to \Omega^{k+1}(X; E)$ by taking

$$\nabla(\omega \otimes s) = d\omega \otimes s + (-1)^{|\omega|} \omega \wedge ds.$$

Consider the composition $\Omega^0(X; E) \xrightarrow{\nabla} \Omega^1(X; E) \xrightarrow{\nabla} \Omega^2(X; E)$. Observe that

$$\begin{aligned}
\nabla^2(fs) &= \nabla(\nabla(fs)) \\
&= \nabla(df \cdots s + f\nabla_s) \\
&= d^2 f \cdot s - df\nabla_s + df\nabla_s + f\nabla^2 s \\
&= f\nabla^2 s.
\end{aligned}$$

Hence $F := \nabla^2$ is a tensor and belongs to $\Omega^2(X; \mathrm{End}(E))$. Note that F is precisely the *curvature*.

Definition. We say that ∇ is *flat* if $F_\nabla = 0$.

Proposition 43. If p_0 and p_1 are path homotopic and ∇ is flat, then $h(p_0) = h(p_1)$. (In this case, we call the holonomy the *monodromy*.)

Definition. Let $\pi^{k/\mathbb{R}} \to X$ be a vector bundle and $\{U_\alpha\}$ a trivializing cover with local trivializations φ_α. A *homomorphism $\psi : E \to F$ of smooth vector bundles on X* is a smooth map such that $\psi_x := \psi \restriction_{E_x} : E_x \to F_x$ is a homomorphism for each $x \in X$. It is called an *isomorphism* if each ψ_x is an isomorphism.

Note 57. Suppose that ψ is an isomorphism. Let $g_{\alpha\beta} = \varphi_\alpha \varphi_\beta^{-1}$ and $h_{\alpha\beta} = \tau_\alpha \tau_\beta^{-1}$, which are maps $U_{\alpha\beta} \to \mathrm{GL}_k(\mathbb{R})$. Note that

$$
\begin{array}{ccc}
U_\alpha \times \mathbb{R}^k & \xrightarrow{\varphi_\alpha^{-1}} & E \restriction_{U_\alpha} \\
& \nwarrow{\scriptstyle \tau_\alpha} & \downarrow{\scriptstyle \psi} \\
& & F \restriction_{U_\alpha}
\end{array} \quad .
$$

Then, on $U_{\alpha\beta}$, we have that

$$
\begin{aligned}
\tau_\alpha \psi \varphi_\alpha^{-1} &= c_\alpha \\
\tau_\alpha \psi &= c_\alpha \varphi_\alpha \\
\tau_\alpha &= c_\alpha \varphi_\alpha \psi^{-1} \\
g_{\alpha\beta} &= \varphi_\alpha \varphi_\beta^{-1} \\
h_{\alpha\beta} &= \tau_\alpha \tau_\beta^{-1} \\
&= (c_\alpha \varphi_\alpha \psi^{-1})(c_\beta \varphi_\beta \psi^{-1})^{-1} \\
&= c_\alpha \varphi_\alpha \psi^{-1} \psi \varphi_\beta^{-1} c_\beta^{-1} \\
&= c_\alpha \varphi_\alpha \varphi_\beta^{-1} c_\beta^{-1} \\
&= c_\alpha g_{\alpha\beta} c_\beta^{-1},
\end{aligned}
$$

i.e., $h_{\alpha\beta} c_\beta = c_\alpha g_{\alpha\beta}$.

Proposition 44. *E and F are isomorphic if and only if there exist a common trivializing cover $\{U_\alpha\}$ with respective transition functions $g_{\alpha\beta}$ and $h_{\alpha\beta}$ and a function $c_\alpha : U_\alpha \to \mathrm{GL}_k(\mathbb{R})$ such that $h_{\alpha\beta} c_\beta = c_\alpha g_{\alpha\beta}$.*

Definition. We say that a vector bundle $\pi : E \to X$ is *flat* if there exist U_α and $g_{\alpha\beta} : U_{\alpha\beta} \to \mathrm{GL}_k(\mathbb{R})$ where each $g_{\alpha\beta}$ is locally constant. We define the flat structures $g_{\alpha\beta}$ and $h_{\alpha\beta}$ to be *equivalent* if there is some $c_\alpha : U_\alpha \to \mathrm{GL}_k(\mathbb{R})$ that is locally constant and has $h_{\alpha\beta} c_\beta = c_\alpha g_{\alpha\beta}$.

Theorem 32. *Let X be a path connected smooth compact manifold. The following object are in 1-1 correspondence up to isomorphism.*

1. *A vector bundle $E \to X$ with a flat structure.*

2. *A vector bundle $E \to X$ with a flat connection.*

3. *A homomorphism $\beta : \pi_1(X, x_0) \to \mathrm{GL}_k(\mathbb{R})$.*

Proof.
   $\underline{(3) \implies (1)}$ Let $\beta : \pi_1(X, x_0) \to \mathrm{GL}_k(\mathbb{R})$ be a homomorphism. Let $p : \widetilde{X} \to X$ be a universal cover. We can form $E_p := \widetilde{X} \times_{\pi_1(X, x_0)} \mathbb{R}^k$, which equals $\widetilde{X} \times \mathbb{R}^k / \sim$ where $(x\gamma, v) \sim (x, p(\gamma)v)$. Consider the map $T : E_p \to X$ given by $(x, v) \mapsto p(x)$. Then each fiber is isomorphic to V.

Claim 5. *T is a flat vector bundle.*

Proof. There exists a trivializing cover of $\widetilde{X}$ with $\varphi_\alpha : \widetilde{X} \restriction_{U_\alpha} \to U_\alpha \times \Gamma$ where $\Gamma \cong \pi_1(X, x_0)$ as $\pi_1(X, x_0)$ modules. Then $\tilde{g}_{\alpha\beta} : U_{\alpha\beta} \to \mathrm{Aut}(\Gamma)$ with Γ discrete. The $g_{\alpha\beta}$ for E_p are precisely the $p(\tilde{g}_{\alpha\beta})$, so that there are locally constant. $\qquad\square$

$\underline{(1) \implies (2)}$ Let $\pi : E \to C$ be a flat vector bundle. Then each $g_{\alpha\beta} : U_{\alpha\beta} \to \mathrm{GL}_k(\mathbb{R})$ is locally constant. A section $s_\alpha : U_\alpha \to \mathbb{R}^k$ has $\nabla_0 s_\alpha = ds_\alpha$. Note that $s \in C^\infty(X; E)$ corresponds to s_α where $g_{\alpha\beta} s_\beta = s_\alpha$. We have that

$$\nabla(s_\alpha) = \nabla(g_{\alpha\beta} s_\beta) = dg_{\alpha\beta} s_\beta + g_{\alpha\beta} \nabla(s_\beta).$$

But this equals 0 because $g_{\alpha\beta}$ is locally constant. Since $\nabla_0(s_\alpha) = g_{\alpha\beta} \nabla_0(s_\beta)$, it follows that the s_α transform correctly to form a global section. Further, it's clear that $\nabla_0^2 = 0$.

$\underline{(2) \implies (3)}$ Given (E, ∇) with ∇ flat and γ a path based at $x_0 \in X$, let $h(\gamma) : E_{x_0} \to E_{x_0}$. This is an isomorphism that depends only on the homotopy class of γ. $\qquad \square$

Proposition 45. (De Rham theorem for local systems) Let (E, ∇) be flat and $\nabla^2 = 0$. Then $(\Omega^\bullet(X; E), \nabla)$ is a complex, and

$$H^*(\Omega^\bullet(X; E), \nabla) \cong H^*(X; \underline{E})$$

where $\underline{E}$ denotes the locally constant sheaf that is defined by the flat structure that E obtains from ∇, i.e., $\underline{E}(U) = \{s_\alpha : U \cap U_\alpha \to \mathrm{GL}_k(\mathbb{R}) \mid s_\alpha \text{ is locally constant and } s_\alpha = g_{\alpha\beta} s_\beta\}$.
